I think I'd rather have the one in the clear. What you can do is
use shorter radials in the directions with less room along
with the longer ones in the better directions. Most of the
ground loss with a monopole is at the immediate base of
the radiator. So the shorter radials should help more than
one might think. But I think it would be worth it to get away
from the wire laden buildings.
Actually, I would prefer to elevate the antenna on a mast,
but I don't know if that is an option.
Elevating gives a much better line of sight, but also greatly
reduces the number of radials needed to reduce ground loss.
If the vertical is high enough in wavelength, one radial is all
you really need for an efficient antenna. Two is the minimum
number needed to have a good omnidirectional pattern if you
run them out ground plane style 180 degrees apart.
One with a single radial acts more like a dipole than a vertical.
If the radial can drop down, you have a half wave vertical with
an omnidirectional pattern, but most will be using metal masts
to support the elevated vertical, and will have to fan it out
ground plane style. And that will skew the pattern a tad, but
not hugely so.

Of course, if you elevated a HF6V, you would need at least
one tuned radial for each band to use it on all bands.

A 4" grinder works fine, but is really over kill.
A Dremel tool is just dandy, cut and round the end easily.
In the field, use a set of linemen pliers.
Put the antenna in the cutting portion, hit the top of the pliers on the
flat surface with a hammer.
Do it smartly and the cut is neat and clean.

As usual, I cannot recall the source, but I read somewhere that the
symmetry and general layout of the radial field (buried radials) has
little effect on the radiation pattern. I do recall that I considered
the source credible.

I think there is a release of the NEC engine that supports ground
models but I don't know if that will answer this question.
Unfortunately it is priced beyond this hobbyist's budget.

There may be more than two choices. Don't overlook placing the antenna
between these two extremes.

Hello,

I bought a MFJ1622 antenna at a flee market, but it lacks some parts : wip
and wiring.
I have replaced the wip by a TR-PP-13 collapsible (military antenna) but I
don't have any idea of how was the original wiring of this antenna.
I tried several kind of wiring and they work , rather well, but I would like
to know and use the original wiring...

Could someone explain to me, how it is made ?

Thanks a lot.

OK Bert, thanks a lot for your answer.

I have already found that manual, but it don't explain the wiring with a schema.

I had found this link : http://www.pbase.com/vr2ham/image/84202109
But I wonder whether it is the good manner, to connect the coax at the bottom of the coil , because I'm afraid that the wire between the alligator clip and the bottom of the coil makes a short circuit which could decrease the quality of the active part of the coil.
I wonder whether the original wiring, wouldn't be not isolated from the bottom of the coil...
Another idea would be that the wiring would be the same that the wiring of the "miracle antenna" which ran nicely at my last tests ?

Minnesota is very similar to Illinois, and seems to be about as corrupt in the way that only long entrenched Democrat machines can be. They're just much nicer and friendlier about it. Which is a great disguise in most cases, and helps the news crews put a positive spin on all the nonsense that happens here.

I think I'll forego the pleasure of dealing with any state level bureaucracies, thanks.

But thanks for the advice, I do appreciate it.

Hello Giovanni,

My first impression is for 80m go for the good ground site and for the upper bands go for the clear area. From a man made noise perspective, I would go for the clear area, but of course this one you can check via S/N ratio of received stations. The clear area may result in less interference from your signal in user equipment.

Regarding the buildings, are they very large in horizontal size and height or do I have to think of just three isolated buildings without any other buildings behind it (seen from the antenna)? If there were many buildings, I would go for the clear area in both cases.

Regarding radiation pattern, I would not worry about this. If you can put the antenna such that you have most of the long radials in two opposite direction only, the effect on radiation pattern is negligible.

For the DX case, you will rely on the vertical component only as the horizontal component will vanish more rapidly under decreasing elevation angle. Your radiation pattern (elevation pattern under varying azimuth) depends heavily on ground properties several wavelengths away from the antenna and you have no influence on that.

Best regards,

Wim

Each cloud has a charge and the all is flowing to the ground. But only 20%
as the direct stroke.

The rule is simple. A mast with the polished ball on the tip attract the
direct stroke (polished ball do not dissipate).
A mast with many sharp spikes dissipate the static charge and eliminate the
direct strike.

> Direct strikes are typically around 20 kA, and can be as high as 100kA.
> Both can be adequately carried by the usual AWG6 wire, because the current
> pulse only lasts a few microseconds.

It is the oscillating current which has a canal in the air. It is not
obliged to flow only in the wire.

wrong, sharp spikes are designed to start an upward streamer that
connects the downward leader to the lightning rod. that is why they
have a sharp point, to reach the breakdown field gradient before
anything else around them.

>

normally they don't oscillate, it is a mono-polarity pulse.

A mast with a ball is less likely to attract a strike. That is why
they are
used on flag poles, etc.. They don't stream near as well as a sharp
point. They can still be struck though if nothing more attractive
is around as far as streamers.
A pointed mast streams much easier and will be much more
effective as a lightning rod.
A mast with a lot of spikes is wishful thinking. You can not bleed
off the charge fast enough to eliminate strikes. It's like whizzing
in a whirlwind.
You can not eliminate a direct strike by bleeding off the charge.
You can only offer it a better and easier streaming target than
whatever you do not want struck. And the sharper and more
pointy an object, the better it streams. When is the last time
you saw a lightning rod with a polished ball on top?
They don't sell them, as they would be fairly useless.

Thanks to all for the good advice. You all agree that the priority is to have the antenna on the clear.
To summarize , I would exclude the option to elevate the antenna because I do not like to walk on roofs or climb towers any more, a ground level antenna is much more safe.
About the ground radials, my understanding is that the RF current flowing in to the antenna from one terminal of the feed line, must return to the second terminal of the feed line that is grounded at the antenna base, and it will do so flowing through the soil in the vicinity of the antenna. If I provide a more conductive path on the soil by laying radials, the electrons will find it, regardless of the simmetry of the system and avoid to dissipate energy heating up the ground.
On the other hand, a building near the antenna is not connected to the second terminal of my feed line and so the RF current captured by the building metallic structures can only be dissipated and playing funny games with the electronics gadgets inside the building.
Now that I decided to put up a new antenna, let's just hope the solar cycle 24 will behave.

Thanks to all
Giovanni

Actually, air terminals with blunt ends and sphere ends have been tested by Erico, and they work about the same as the traditional "Franklin" style with the pointy end.

> They don't sell them, as they would be fairly useless.

That's not because they work or don't work, it's because fashion dictates pointy end. You'd have to have a substantial performance improvement to justify something different (i.e. to be unfashionable, it had better give you something else).

At the fields in play here, whether you have a 1/10" radius or a 1/2" radius or 3" radius, it doesn't make much difference.

the breakdown voltage for a curved surface is roughly 3MV/meter or 70kV/inch.

So a 1/2" diameter rod (1/4" radius at largest) will breakdown at about 17-18 kV. A 6" diameter ball breaks down at 200kV or so (assuming it's perfectly smooth, etc.)

The "free air" electric field without a storm around is on the order of 100 V/meter, rising to 10-20 kv/m under a storm. So, get 10-15 meters up, and you've got your 200kV needed to start corona on even a pretty big diameter thing.

If the ball is wet, especially with distinct droplets, then you can get corona forming much earlier. The electrostatic forces tend to make the droplets fly off.

Non-rhetorical question(s).

I must be missing something then. Why don't I see corona on the tips of leaves at the tops of my trees? Trees are pretty conductive when hundreds of kilovolts are involved.

Or my antenna masts for that matter, 'cause they are grounded, too.

For Franklin it was obvious: "This grew into his idea for the lightning rod.
Franklin described an iron rod about 8 or 10 feet long that was sharpened to
a point at the end. He wrote, "the electrical fire would, I think, be drawn
out of a cloud silently, before it could come near enough to strike..."

But somebody want to catch strong lightnings:
"Blunt-tipped lightning rods are intended to intercept rather than to
prevent lightning strikes. They are intentionally located at the point of
maximum dielectric stress. (See Figure 2). " From:
http://www.nottltd.com/article.html

you like quoting stuff off the web don't you... too bad you don't
understand the basic physics behind it. no, the spark current doesn't
have to oscillate to be picked up by a radio receiver. The short
pulse, yes even one that doesn't oscillate itself, is made up of a
large number of sine waves added together, it is those that can be
picked up by radio receivers. it is also possible at a large distance
to determine the polarity of the lightning stroke as they can be
either positive or negative strokes, that type of distinction wouldn't
be needed if they oscillated.

Electrons like oscillate. The natural oscillations go up and next decay.
Each next jump is stronger at the beginning and weaker at the end.

Lightning jumps from the higher voltage area to the lower. It means that
netto electrons flow always from cloud to earth. But before such are many
lightnings cloud to cloud. Sometimes (5%) are cloud-earth-cloud.

In the all cases the current oscillate.

Yes. I mix the oscillating with pulsating: "Years later, Lodge realized that lightning is not an oscillatory discharge but is actually a rapidly pulsating unidirectional (dc) discharge.[2] However, the effects of the inductive reactance on the flow of these pulsating lightning currents is the same as Lodge predicted for oscillatory currents" From:

In Art's equilibrium and Michael's "truds" are more sense than in yours
"magnetic whirls".
All radio history apply to the longitudinal electric waves (Tesla waves) in
wires and in the space.

Lodge made the long wire antennas (see Fig 2):
http://www.antiquewireless.org/otb/lodge1102.htm

The sparks are rather harmfull for transmitting. The better is a field
emission of electrons ("truds" or the "time dependent Gauss law").

You are an expert.
Does antenna radiate if it is coated with the thick good insulation?

Unfortunatly the coherer do not work nowdays. To much electric waves in the
rare plasma.

But the Lodge's "electrical radiation" ("time dependent Gauss Law") works.
"Lodge then added a postscript to his own paper acknowledging Hertz's work
in an extremely positive way. He concluded the postscript by saying: "The
whole subject of electrical radiation seems working itself out splendidly".

In the clear air field (the 100V/meter sort of thing), you're not going to see corona, because the voltages aren't high enough.

In thunderstorm type fields, you would see corona, if you look closely. There's an interesting paper (which I can't find right now, but I'll look) where someone measured the current from a field of wheat.

Not all breakdown will produce visible corona.

If you have a resistive thing (i.e. a tree), covered with sharp points, then the object tends to adopt the overall voltage profile surrounding it, so there's not much net difference in voltage between the leaf/needle and the surrounding, so the field isn't locally high, so there isn't any breakdown.

>
> Or my antenna masts for that matter, 'cause they are grounded, too.

You probably DO have corona breakdown, it's just not noticeable. It's kind of a challenge to measure microamp currents in a 100 foot tower. And if that milliamp or microamp is spread over a large area (i.e. your tower isn't a smooth machined surface with only the one point having small radius of curvature) then it would be less noticeable.

St. Elmo's fire and corona discharge are distinctly different, although
St. Elmo's is often described as corona, it actually isn't.

Yes, corona in high fields does sound like hissing or buzzing. Anyone
who has been on a high mountain in a thunderstorm has probably
experienced this, and even more exciting is when you get corona
discharge off your hair standing on end.

St Elmo's is a bit different. It has a distinctly different appearance:
a sort of bluish glow that extends some distance surrounding the object,
as opposed to corona, which seems to be "stuck" to the surface. And then
a high field streamer discharge is still different. If you've seen both,
it's noticeably different, but hard to describe.

As best can be determined, St Elmo's arises when the surface of an
object is wet and in a field. The water sprays off the surface (much
like is done in electrospraying), and the droplets carry charge away.
Several different things then happen: 1) The charge causes the droplet
to break apart into smaller droplets from electrostatic forces; 2) the
field at the surface of the droplet is now too high and the air
breaksdown at the surface of the droplet, discharging it, and 3) the
droplet starts to shrink from evaporation, getting smaller, so the field
at the surface grows, etc.

So St. Elmos is not really corona off the object, but corona/breakdown on the droplets being electrosprayed off the surface.

It is possible to generate St. Elmo's in the lab on the surface of an object with fairly large radius of curvature (i.e. that would NOT be subject to surface corona) in a moderate field. If someone wants to try an experiment, put a wet cork or dowel of wood in a shallow tray or puddle of water with a large flat electrode suspended over it to create the overall field. A field of 10kV/cm will work quite nicely. I used two baking pans separated by cut down styrofoam cups driven by a small modular HV supply (50kV@ a few mA) driven by a variac. Make sure you have a resistor in series with your HV supply, because occasionally you'll get a flashover, and you want to limit the current.

All this is fascinating, especially with presence of water.

All this phenomenon occur at higher voltages. In normal transmissing no such
spectacular glows but only simple field emission.

In textbooks is wrote that the electron emission is more effective than the
absorption and that the glow is different.

Do you know how is the netto flow (field emission/absorbtion) of electrons
during transmitting?

In regards to radiating RF energy, the only difference insulation makes
is the elements are slightly shorter due to the change in velocity factor.

Insulation makes an antenna heavier, can reduce corrosion, and can allow
you to have whatever color antenna you want.

So define "better".

If you mean work as an antenna, there is no difference.

You are a babbling idiot.

even infinitely thick insulation allows radiation.

If the insulation is infinitely thick, there is no outside of the insulation
where radiation can occur.

But, yes, there will be radiation inside the insulation.

Like vacuum. But there are ions and free electrons.
In solid and liquid insulators no free electrons.

Does solid insulation makes the radiation weaker or stop it?

Glass is an insulator but it is transparent for the light frequencies.

Does exist an insulation (reasonably thick) which is not transparent for the
radio-amateur frequencies?

You obviously do not know that the amateur frequencies start at 1.8 MHz
and include everything above 300 GHz.

Within that range of frequencies, there are lots of materials that are
"insulators" that have large dielectric losses.

See:

http://en.wikipedia.org/wiki/Permittivity

and in particular:

http://en.wikipedia.org/wiki/Permittivity#Lossy_medium

You are a babbling idiot.

Interesting, thanks.

That is similar to some of the new systems that let you store encrypted
data and perform operations on them without decrypting them or knowing
what you've done.

A couple years back, (after I had the system pretty well finished) we
had one of those multiple strikes. It hit the power line out front,
but neither I nor my neighbor directly across the road had any
problems. However the neighbor to the North of him lost a lot of
equipment. To that South of that neighbor across the road is a vacant
lot that *had* a pine tree at the back of the lot. That tree
literally exploded. All that was left of a 50 foot tree was a a 4'
stump and a LOT of splinters. Well there was one piece about 4' long
(give or take) stuck into the ground about 60 feet out. Thing is,

only a little of it was sticking out of the ground. That thing must
have had a LOT of force behind it.

" For frequencies at which dipole orientations cannot follow the applied
field due to the viscosity of the medium, absorption of the field's energy
leads to energy dissipation"

> You are a babbling idiot.

I am collecting evidences. Thanks for your input.

So, next question:

The "energy dissipation" means heat.

In case of the bare wire the air is heated. For isolated the insulation.
Is it possible to burn off an insulation which have large dielectric losses?
S*

I suppose yes, if the loss is high enough, and the applied power is high enough. However, a dielectric that lossy would greatly effect the electrical length of the antenna element, and removing it would change the characteristics and impedance of the antenna, so it may totally change the way your antenna behaves.

Jeff

3279. Antenna Question: VHF or UHF, and a few general TV questions, please

Newsgroup: rec.radio.amateur.antenna
Date: 2010-07-29 12:16:42 UTC
From: Bob <rgsros@notme.invalid>
Message-ID: <i2rrfi$u0h$1@news.eternal-september.org>
Source record: 8129

ello,

Am in my 70's now, and frankly not all that sharp with antennas.
I figured someone here might be able to help me out.

Live about 25 miles due west of Boston.

Have an old fashioned analog TV in the kitchen (not on cable)
that this question relates to.

Some time ago, as you know, all the TV stations required one to get
a Converter box. Did so, and am using it with an old fashioned,
el-cheapo indoor antenna; the one with the rabbit ears, and a loop.

The Converter box feeds my analog TV.

Works "fairly well," but lots and lots of dropped signals.
Makes listening very unpleasant.

It has been recommended that I purchase a:
DB-2 antenna for about $ 35.00

This is shown in (please take a look):

HDTV Antennas

http://www.antennasdirect.com/store/DB2_antenna.html?pconf=55&slot=68

http://www.antennasdirect.com/store/pconf.php?productid=55DB2

Questions:

a. Are these new, converted, stations now transmitting in the vhf or
uhf ?

e.g., am I after a new, better, vhf or a uhf antenna ?

b. Do you think that this DB-2 would be worth trying ?

Any thoughts would be most appreciated.

Thanks,
Bob

Bob,

Except for a few low power or educational stations you just need a UHF
antenna, and the DB-2 looks like a good choice.

Hello Bob,
I understand the age reference, I turned 70 in April.

The antenna you are looking at is a tried and true UHF Bow Tie. It is definitely better than rabbit ears. However, it is pretty bulky for indoor use. Since you are getting a poor picture now, I would guess that it is likely that this would do the job. The twin lead wire that they offer is lower loss than the coax cable. The twin lead also allows a old fashioned tuning trick: Wrap a small piece of aluminum foil around the twin lead and slide it around for the best signal. That might help your existing Rabbit ears as well!

A better Bow tie can be fashioned from hardware cloth (tighter mesh) and wire. The dimensions are not very critical and if it is to be used inside weather proofing is not a concern. Think in terms of tape, foil any kind of wire. Clothes hanger wire is usually handy.

Thanks for the reminder, I need to try a couple of long dormant ideas!

Yeah, so what?

You do understand that they are referring to the molecular dipoles in the
insulator, don't you?

>> You are a babbling idiot.
>
> I am collecting evidences. Thanks for your input.

Evidences (sic) of what, that you are a babbling idiot?

> So, next question:
>
> The "energy dissipation" means heat.

Of course.

> In case of the bare wire the air is heated.

Nope.

This just shows you have no idea what permittivity and conductivity mean and you haven't a clue what you are babbing about.

> For isolated the insulation.
> Is it possible to burn off an insulation which have large dielectric losses?
> S*

If you had the slightest understanding of the very first equation of the referenced link and the text that follows, you would know the answer is yes.

Since you apparently read the link and still asked the question, I can only conclude you are an idiot.

Hi Bob,

Good starting point.

>Works "fairly well," but lots and lots of dropped signals.
>Makes listening very unpleasant.

Only means you need to move your existing antenna HIGHER.

>It has been recommended that I purchase a:
>DB-2 antenna for about $ 35.00

If you want to spend $35 and mount it HIGHER, you can do that too.
[The implication here is you will probably need an external set-up any
way you look at it.]

If your rabbit ears need to be turned to capture the best signal, then
you may need to do this second option. Don't forget the expense of a
mast and cable/wire to go between things. If you still need to turn
the antenna, then you need a proper rotor and mast (with a bolt to the
side-of-the-house kit). Somehow, given your location I would suspect
all the major broadcasters would be on the same general beam heading.

Getting the antenna (whatever you choose) higher recovers from a lot
of ills.

As you know I do not understand why in XXI century most scientists use the
hydraulic analogy.
Permittivity and polarisation are from the hydraulic analogy.
Now conductivity and electrostriction should be used.

Bob-

It depends on where you are. There is a web site that has that information, along with pointing information from your location. I just can't recall the URL due to Old Age!

I think we all are experiencing the same problem with HDTV, regardless of whether we have a converter box or an HD set. Unless you happen to be close to the transmitter site(s), you probably need an outdoor antenna, as others have suggested. I'm using a simple attic-mounted VHF/UHF antenna with an amplifier, but still have dropouts when a low-flying airplane passes.

I just found the URL listed on the plot for my local TV stations as: <http://www.tvfool.com>.

Hi Guys,

Just a quick thanks for all the really good info.
Nice of you all to take the time; appreciate it.

BTW: That DB-2 I mentioned is really large for anywhere but an attic.
Didn't realize the dimensions of the thing.

The rabbit ears we now have are on the top of our fridge, and not too
obvious. Running a wire from the attic may not be practical, for now.

Any suggestions on anything possibly worthwhile to try, smaller than the
DB-2 ?

Thanks again,
Bob

3289. help with antenna grounding

For a variety of reasons I have to place a roof tv antenna smack in the middle of my roof and the ground wire has to run the most direct course straight of the roof and straight down to the grounding rod. the coax however has to run across the roof in a different direction to the service entrance where it will be run through a grounding block. So there will be 2 separate grounding rods sparated by about 60 feet. Will this cause anything like a ground loop??? Does anyone know if this is code to have 2 different ground rods?? thanks for any help. jk

>DB-2 ?

Hi Bob,

FIRST, your objective should be height, the ability to "see" the city (or, more specifically, the transmit towers: consult the other posters on how to locate them).

SECONDLY, you select the antenna that does the job. As your rabbit ears nearly work, they might fully work up on high.

THIRDLY, how high is a matter of many practical issues. Hence the suggestions for attic locations by others. This is an easy first test that costs no more than the length of cable/wire necessary to go there. You will need the cable/wire anyway.

FOURTHLY, if your antenna at the desired height doesn't work (which, in effect, is your original complaint), then throw money at it in the form of amplifier, antenna, mast, mounting hardware, and rotator (you never revealed how up to speed you are in knowing where your broadcasters are).

It will cost more doing it in the expensive order (buying the antenna first, and possibly a second one when the first doesn't work, etc.).

I don't know what the code in your area would require, but the two grounds in my area are required to be connected together and to the house ground and to the cold water pipes. The idea is not to have anything at a different potential when struck by lighting. If everything is at the potential, nothing will be damaged or that is what is supposed to happen. In my case my tower is 65 feet from my ham shack. The tower is grounded with a ground rod to each tower leg. The feed-lines run into the shack in a buried 4" plastic conduit. Along the outside of it is a #6 copper wire connected to the tower which is ground along it's length with 4 more ground rods. The #6 wire comes into the house and crosses across the house to the entranced panel were it connects to the entrance panel ground and along the way connects to the copper panel were the lighting arrestors for the coax are located. The code inspectors loved it. I would think that a wire from the ground rod that is connected to mast to the entrance panel and to the house electrical panel ground would be the thing for you to do. And no there is no problem with ground loops. This ground is for lighting protection only and is of no use for RF ground an it has too high of an impedance for RF.

Hi Bob,

The ears are for VHF, the loop is for UHF. Neither are critically adjusted - aside from your effort on the ears; and even there, few choose or find "classic" lengths. If I am to guess correctly (by inference of your old TV/antenna), then I would say you were reasonably served by the Boston channels in the past. This suggests that you are probably just on the fringe of the newer technology's lower power transmission.

The antenna you have now is not suited for outdoor environment (you could probably guess this). However, if you first invest in a suitably long enough cable/wire and go outside with it mounted on a broom stick and climb a ladder to do a survey around and about, then this will give you a first-pass guesstimate of how much effort you will need to put into this project. This test will lack in stability of position, and the ability to trim the lengths of the rabbit ears, but I bet it will give you enough information.

That babbling idiot hasn't a clue what ANYTHING really is.

If you read sci.physics.electromag you will find lots of his gibberish.

3298. Survey

Newsgroup: rec.radio.amateur.antenna
Date: 2010-07-30 19:33:42 UTC
From: M0WYM <nospammers@radiowymsey.org>
Message-ID: <i2v9ep$n4g$1@news.eternal-september.org>
Source record: 8148

Twenty average members of the public were asked what they thought of
radio amateurs:

9 said amateurs were the cause of interference.
3 thought amateurs were nut cases.
5 said amateurs were odd but harmless.
3 had never heard of radio amateurs.

Five top people in the electronics world were asked their opinion:

3 would not employ radio amateurs in their organisation.
1 had heard amateurs on air and opined that they spoke a load of tripe.
1 said that most technical blokes talked a load of tripe anyway.
1 said he would employ an amateur if qualified for the job.

That was in 1965, so not much changes or does it?

Charlie.

If you think that's bad, you should see what they say about people who
cite bogus surveys on the newsgroups!

Ha ha,

Not bogus thought but from the April 1965 edition of the Short Wave
Magazine but I did post it to the wrong group!

Charlie.

really is?

It is not the dipole orientation (rotation). It is the deformation of the
dielectric.

"In fact, most dipolar solids exhibit extremely small dielectric losses
since W tends to be extremely large. Water-free ice, for example does not
heat significantly under microwave irradiation." From:
http://www.tan-delta.com/mw_heating.html

Water droplets are strongly deformed in a weak electric field.
Do not stay in the Heaviside water. There the two electric fluids were
displaced. No deformation of shape.

Now many scientists analise the electrostriction.

"Quartz glass has a very high dielectric strength but a very low electric
conductivity, even at high temperature, high voltage and high frequency,
nearly without electric loss in the range of the frequencies applied.
Therefore quartz glass is an excellent high temperature dielectric
material."

What is the cause: polarisation or electrostriction or the both?

I wish he would talk to art more, the two of them are more fun when
they are combining their gibberish. i guess they just don't realize
that the technobabble they have come up with doesn't really mean
anything useful, and little pieces of knowledge taken out of context
just can't be strung back together in any order to prove something
they think is right.

so which of these do you think may apply to Mr. B or Art? Could be just about any of them i guess, though art seems to alternate between Logorrhea and silence, maybe he's bipolar? Mr. B seems to be solidly Schizophasiac, just continual nonsensical babbling.

Wernicke's aphasia
Schizophasia, a mental condition characterized by incoherent babbling (compulsive or intentional, but nonsensical)
Logorrhea (psychology), a mental condition characterized by excessive talking (coherent or otherwise, but compulsive)

3311. Crossposting Permitted to rec.radio.amateur.moderated

Newsgroup: rec.radio.amateur.antenna
Date: 2010-08-01 06:00:03 UTC
From: rram@panix.com
Message-ID: <radio/ham-radio/moderated/crossposting-1-1280642401@panix.com>
Source record: 8161
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.amateur.policy,rec.radio.amateur.space,rec.radio.info

```
Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

3312. What is the low end of a band?

Newsgroup: rec.radio.amateur.antenna
Date: 2010-08-01 08:59:34 UTC
From: barett <barett@blueyonder.co.uk>
Message-ID: <LHa5o.5855$7Z3.5790@hurricane>

I am thinking of making a new antenna but in the info it talks about, if the SWR is high on the low part of the band.

In the 20 meter band are they referring to 14.000Mhz end or the 14.350Mhz end of the band as being the low part of the band?

Any help please.

Thank you

The question was: "Does solid insulation makes the radiation weaker or stop
it?"

Instead the answer you serve me the word salad.

it will not stop it, it might make it stronger or weaker depending on
the loss characteristics and what you measure as the strength.

When talking about the swr and low end of the band, that is the lower frequency part of the band. In your example it would be the frequencies near 14.000. Frequencies near 14.350 would be the upper or high end of the band.

It can be confusing as when you hear 'top band' referred to that is usually the 160 meter ham band. Guess that it got that way because the 160 meter is the highest ham band in meters even though it is the lowest in frequency.

What is really confusing is what is meant by a statement like: "This
antenna only works well above 40m."

It literally means that the antenna only works well at frequencies
below 300/40 = 7.5 MHz, but that is not what most hams mean when they
say it.

And what with the "natural" insulations: the ice and the wet?

Sometimes are on your dipoles an ice or water.
They should melt/evaporate in the places where are picks of the voltage.
Is it observed?

Lodge observed the glows. So there should be the heating also.
Burn off an insulation needs more heat than melting/evaporating of
ice/water.

And the question has been answered many times now by several people.

In the real and practical world, no, insulation will not stop the radiation
from an RF antenna and depending on the frequency and material of the
insulation some of the radiation will be aborbed as heat by the insulation.

What part of the words "insulation" and "insulator" do you not understand?

There is nothing special about ice or liquid water and the electrical
properties of both can be easily looked up.

There is nothing mystical about something that is "natural".

You assume that everything "can be easily looked up". It is right for the
old theories.

But now is the new Art's "time dependent Gauss law" theory.

At the ends of the dipole the alternate electric field is produced. There is
the Lodges glow.

So it is interesting if that glow is also visible on insulated wires and
what is emitted from the antenna.

You have opportunity to develop the Art's theory. Do not be lazy.

i suggest you talk to art about art's theory, the rest of us on here
know that it is pure garbage. for your information gauss's law has
always been time dependent, art just doesn't understand that and
insists on rewriting and reinterpreting it. he is wrong, and you are
wasting time trying to follow him... but then again you are wasting
your time on just about everything you write on here anyway.

You're missing something very important here, and you ask for the
information and then discount it when it doesn't satisfy you.

The MEASURED CHARACTERISTICS of something cannot change just because the
theory explaining it has changed.

And it is quite easy to find. I'm surprised since you seem to be able
to find all the esoteric explanations of how the world works.

Your brain is broken, get it checked.

Yes you can.

Some RG-6 cable has an aluminum shield and can not be soldered to if that is
a problem for you.

In June, we had a long discussion of RG-6 coax, the proper connectors to use for it, and how well it works.

To recap, you need to buy COMPRESSION connectors and the correct tools for them. "F" connectors are used all over the world in the cable tv and satellite industry. F to UHF (aka PL-259) adaptors are available and work well.

In my case, I have a cheap source of BNC to to UHF adaptors, F to UHF adaptors are hard to find and expensive. So I use compression BNC connectors for those ends.

Geoff.

I can find milions papers on the theory of glow and losses in AC network.
The same should be for the radio frequences.
I was thinking that somebody from you have a link to such.

The AC glow is not simmetrical. So in the radio transmitter must be the
netto electrons flow.
Where can I find the DC ground current?

Are you assuming that because there is high voltage, there is current
induced heating?

Voltage does not translate diresctly to heat.

When is everyone going to wake up. What we need is a USB dongle which is simply a recvr/xmitter and is software driven. This is the last "cell phone" you will ever need to purchase. It can incorporate an onboard antenna, however should also have an external ant connection so in fringe areas communication is improved.

Isn't it about time we stopped buy a seperate TV, radio, phone, stereo, etc. A computer with the proper software and attachment(s) are all of these and more.

It is time to end the stone age of electronics!

Bill Miller calls it "the transverse current". Electrons must displace
perpendicular to the antenna surface in AC.
In insulators are the electric losses.
>

In insulated antena are the transverse current and the displacement current.

The all are facts. Should be easy to observe.

Some topics ago somebody analised the antenna temperature.
The end of the dipole should be the hottest.

Have you any observations in this subject?

Hello Alejandro:

If you can solve the mechanical issues, yes you can.

When it has an electrical length n*0.5lambda (n= 0, 1, 2, etc), VSWR
will be exactly the same as with a 50 Ohms cable. With other length
(especially 0.25, 0.75 lambda, etc) length, you may get change in VSWR
(can be both better or worse).

When your dipole is about 50 Ohms (antenna side), just match it at the
transceiver side if required, and don't worry about the cable loss due
to VSWR inside the cable. When the antenna itself shows VSWR=1 (based
on 50 Ohms), your VSWR at the transceiver side should not be worse
then 2.25.

You can use same common mode current suppression techniques (balun,
ferrite common mode chokes, trap, etc) as with a 50 Ohms cable.

Best regards,

Wim

Is a quantum effect current flow, and does heat emit from the process?
If it isn't heat induced, the effect is almost certainly ionization.

Aside from analysis, has anyone measured this effect?

Is it to be expected in highly efficent antennas, or just inneficient
ones in which there is substantial heating already?

Is this assuming that the heat if given off is enough to raise the
temperature surrounding th eantenna above 0deg C?

No it isn't. I don't want to take calls on my television. The XYL will talk for hours with friends. Seems like a bad thing to tie the TV up for that time. I don't want my telephone to be my computer either, or listen to my music on my telephone.

It's for the same reason that I don't want to keep my frozen meat in my car. A whole lot of us prefer our devices to be purpose built instead of the myriad of compromises in having all in one instruments. History has shown that all in one devices tend to perform poorly or mediocre at best in all their functions.

They kind of remind me of the Escalade SUV/Pickup trucks. Horrible pickup truck, poor SUV, and ugly as sin.

> It is time to end the stone age of electronics!

I want faster, better looking, and higher performance. I don't want all-in wonders, which are always compromises.

Only a damn fool would make a phone call on their TV, or even think
about it. But, if the case is you and the wife can't afford seperate
hand-helds/netbooks, well, get a better job!

Again, only a damn fool would think about keeping food in their
palm-top/ereader/netbook, or even think about it. Hmmm, my computer is
not a printer, but an external printer hooked up workes just fine. My
computer is not a netcard, but a USB dongle netcard works just
fine--plugged in, my computer is not a TV, but an USB dongle HD TV works
fine--plugged in, etc. In fact, I have never noticed any problems with
them running all at once. Perhaps you need new hardware.

> They kind of remind me of the Escalade SUV/Pickup trucks. Horrible

Never seen wheels, steering wheel, gearshift, headlights, etc. on a
palm-top/ereader/netbook/laptop/computer. This sounds more of mental
condition and/or drugs.

I also plan to use the 75 ohm cable to feed a vertical for 20 meters 32ï¿½
high, that is to say aprox. 22 feet.

With that high, the impedance is 100 + i145 ohms. The reactance is
inductive and I will tune it out with a 80 pf capacitor in series made

with the same cable.

The feed line will be 1 +1/4 lambda so at the input of the line the impedance will be (75 x75)/108 = 52 ohms

The 8 radials will be 4 feet long with loses of aprox 5 ohms, so efficiency will be near 94%.

Problem with all that is the dipole may be closer to 70 ohms than it is to
50 ohms. With 70 ohm cable, the swr will be close to 1:1. However most swr
and wattmeters that I have seen are for 50 ohm systems and will not show the
actual swr.
Cable losses with an swr of less than say 2:1 will be low enough not to make
any differance in the real world.

You are a godsend to the hardware manufacturers, they love you!

My TV, radio, stereo, MP3 player, DVD recorder/player, etc. all travel
in my briefcase as USB Dongles or software. That size fits me well! ROFLOL

To each his/her own,

It's a functionality question not a financial question. Should a
second computer with all the USB peripherals be required just so
Mike's Mrs. can use the telephone while he watches television? Being
able to do something doesn't validate its worth. Using USB devices for
the sake of using USB devices gains no efficiencies.

Yourself as well, your USB spell-checker doesn't appear working
properly ;)

Your initial post alluded to convergence but all you're doing is daisy
chaining peripheral devices. The only visible difference between now
and ten years ago is the number and types of available USB devices.

All those peripherals may work well together until disk, bus and/or
processor activity becomes intensive. Regardless of optimism there are
always limitations.

>> They kind of remind me of the Escalade SUV/Pickup trucks. Horrible

You missed the point and taking a second cheap shot won't help you
find it. The Escalade is an analogy about multi-purpose devices in
general, not about using a computer as a multi-purpose device.

If you've never seen wheels, steering wheel, gearshift, headlights,
etc. on a computer you haven't looked at today's passenger vehicles.
There's more processor power there than on/under your desk.

>palm-top/ereader/netbook/laptop/computer

I have not any possibility or opportunity.
Years ago I asked about the frequency doubling. The second answer was:
Luxembourg efect. It was this what I was
looking for.

But next were two hundred post with word salad on me and non-linear effects.

With the "polarisation" was the same.
So I know that sooner or later appear the valuable information.

Michael wrote: "Is it to be expected in highly efficent antennas, or just
inneficient ones in which there is substantial heating already? "

Lodge has seen the glow. You use the LED and VSWR..

Now everybody from you can measure the electron emission and heat emission.
I was expected that you (radio people) know the results.

I do not know. I am asking you (antenna owners).
Working antenna is hotter than at rest. Which part of the dipole is the
hottest?

It sounds like you're describing my 3 y.o. laptop that has all that
hardware built-in. To use the box and all the devices it is simply a
matter of booting up. There is no need to unpack and connect a bunch
of peripherals. When done I can close the lid and go w/o the need to
disconnect and re-pack a bunch of peripherals. It's much closer to
being an all-in-one device than your box with all its external
accessories.

You might want to refrain from using the term 'USB dongle' to describe
anything that plugs into a USB port.

So how does your Television/radio/phone/stereo work exactly? If a person using the phone at the same time as another person trying to watch TV and another wanting to listen to music isn't going to conflict, I'm not sure what will. You be the one that suggested we should be buying singular devices and plug dongles into them.

As you will. My purpose built hardware has one huge advantage. A lot of people have a whole lot of trouble keeping their computers running. I spend a lot of time as my friends and family's Tech support guy.

Explain how having a PC, with all it's security issues and other problems, like updates that knock it out of commission, is going to be a superior alternative to a television that you turn on, or a phone you

pick up and use. When your computer is zombified or halted due to all the spyware on it, it will take down everything that is attached to it. After that, we have to worry about turning our Televisions, which at this time have a 15 year lifespan, into the 3 or 4 year lifespan of PC's. I can just see children waiting patiently while Dad reformats and reinstalls the system software because the computer got hosed and no one is getting anything on the television.

So people are going to have to become IT weenies so they can watch TV? Good luck with that one.

Whoosh. Another analogy about devices that try to be more than one thing. A television is not a telephone is not a cell phone is not a stereo system. One could be pressed into service as all of the above, and at the same time - but it takes a pretty good argument to say it will perform as well as the separate devices.

I use 'em by the ton. My computer controls my radio via Ham Radio Deluxe. I use DM-780 for my digital modes. The computer control of the radio takes place over a USB to serial Dongle. I also have a TinyTracker interface via another USB to Serial dongle. It works pretty well. But I'd never dream of plugging a MagicJack or watching Hulu on it. I have other computers for that stuff.

Not only would performance drop off, but there would be useage conflicts also. Right now, I can watch Television on my TV, while reading email on one of my computers, while carrying on a PPSK31 QSO with the rig control computer. Heck I could carry on a simultaneous conversation via phone too, I guess.

Much more difficult to do all the above if I was using all in one operation.

Well then, sounds like you are on the right track, headed in the right direction. It just takes some a bit longer than others. I am sure you will get it right ... eventually. Anyway, will give you something to do while we are waiting for a software controlled cell phone to be developed. But like I say, it probably won't happen until enough people become "electronic literate" enough to demand them.

Yeah, I can see how you would have a lot of time figuring that out. It
is done with multiple computers. Home entertainment systems is run off
a desktop. Portable stuff done around the home is done on a laptop.
Stuff in a hotel room is done on one of the travel netbook/laptops.
However, I frequently have the tv in a corner of my screen, muted, an
MP3 playing though USB wireless headphones, a call going over skype or
another such application, and the software defined (SDR) radio
monitoring, etc. So the conflicts you keep coming up with are just
unknown here. Perhaps you are just one of those people who can only do
one thing at a time?

Yeah, that is a real pain. You do have to learn to properly
use/maintain a computer. I am always amazed at the amount of people
standing around calling a tech for some simple "plug it in" answer to
fix it. Usually, these are the first to tell you about all the
technically complex stuff they are doing on their computer, like your
text here starts off, then you find out it usually set non-functional in
a corner with them afraid to touch it, in fear of messing it up, ROFLOL.

The above just proposes a lot of problems which don't exist in my world.
My computers run rock solid. If a kid messes with a control, or
causes a problem in the software, I just fix it. Obviously, you need a
computer course, or two, or three, ... and knowledge in the correct
operation of computers. I use Avast free anti-virus. McAfee, Norton,
etc. are just too buggy--there is a problem with these products.
Microsoft defender is an excellent addition to this.

That is just a blatantly stupid remark. The computer was meant to do
all this and much, much more. It is that single-device-single-function
mentality which manufacturers have hired madison avenue ad men to sell
you at work.

That is exactly what they were, have always been, and still are. The
term was coined back in the early 70's and used to be applied to
differing externals plugged in to differing ports of a computer. I
guess you learn something new everyday.

Well, JS. Why don't you design and implement this system. You don't like my logic, and I am "wrong". I say it won't work, and gave my reasons. Prove me wrong. Along the way, you'll become the richest man in the world.

I say people have enough trouble with their computers already to have everything they own running on one. Because it won't be running. There is no reason to believe that this setup you propose will be any more reliable than what is already out there, and not being reliable now.

It isn't vision, it isn't being a Luddite, it's just that it isn't practical. My Television is already accessing the internet. It's doing it via software that isn't Microsoft Windows based, and avoids all the vulnerabilities that platform has. My Telephone is IP based, and the same for that. It works, it's not Windows. The weak point of my entire home communication system is the computer internet access. And if you don't have any trouble, you're one of the few. My Linux machine doesn't have any particular problems, my Mac runs bareback. My Windows PC has to be locked down like Fort knox. It's hard to imagine giving up my presently operating systems to migrate to the weakest link of the chain.

But by all means, have at it. Remember us little folk.

My favorite part about Windows users is when I note a problem, they say "Gee, I've never had a problem with my machine - it works flawlessly. THen they start to tell me about the time a virus got into their machine, and they ended up reformatting the drive and reinstalling Windows, and the time they got their DLL's messed up and ended up reformatting the drive and reinstalling Windows, and the time their machine was zombified and they ended up reformatting the drive but it was rootkitted and they have to reformat again, and then figured out they had a problem in the BIOS. But they've never had a problem.

Even those who have a running computer don't know exactly what's on it.

I deal with repairing this stuff every day, and I have to tell ya, there are a lot of intelligent people that for whatever reason, can't keep their computers running.

Anyhow, have fun, no use of you arguing with the great unwashed like myself.

A major CAD (computer assisted drafting) software company made that a
popular term for its' copy protection. Anyone coming though an industry
heavily dependent on such, and working is such a department, would
certainly share your view. This is much the same as the term "Computer
Hacker"--used to denote one who is tops in their field; This term was
usurped by the news and now in joe-blow-six-packs minds is associated
with computer criminal. Their error.

After VAX boxes and other minicomputers appeared, many types of
commercial productivity applications besides CAD tool relied on
dongles as security devices. As computers moved to the desktop this
did not change. There was even a C-64 accounting application that
required a dongle. It was primitive but effective security.

>This is much the same as the term "Computer
>Hacker"--used to denote one who is tops in their field; This term was
>usurped by the news and now in joe-blow-six-packs minds is associated

Not quite. Journalism isn't the only field where hack writers can be
found. Quick and dirty code is often referred to by the author as a
being a quick hack. It's an acknowledgement that the code is not
particularly elegant or robust, just a temporary solution to resolve
an issue or answer a question.

If a computer professional describes them self as a hacker today
(without using the word hat), it's an admission their skills and
training could be better. Calling any computer professional a hack is
a insult.

Absolutely could not disagree with you more. I do all computer languages (Assembly, Cobol, Snobal, BASIC, C/C++, Pascal, etc., etc.), but prefer assembly and C/C++. Only hackers (doctorates) work within my circle. We all enjoy being called hackers, we worked hard to win that title. Anyone in disagreement works for some corporation practicing security though obscurity, i.e. part of the security are dumb-ed down software engineers. Or, is a member of the joe-blow-six-pack club which watches the 11 P.M. news.

Let me cut to the chase, there are four types of dongles, in the context we are discussing. One will plug into a computer port, the other is in my pants, the third type is obsolete, the forth is walking around with similar characteristics to the one in my pants. ROFLOL!

I did no such thing. Make a computer a cell phone ... or any damn other thing you wish. USB dongles are the quickest/cheapest route.

It takes too much time to keep correcting your errors in text, thinking, etc. Go play with someone else not ...

If the junction with the transmission line is poor.

As you see I cannot accept your answer because it do not fit to Tesla's
radio. So the next question:

The simplest dipole is made from a transmission cable. It is enough to
stretch the wires in the oppsite directions (like arms).
The no junctions.

Which part is the hottest?:
-Transmission cable,
-The first part of the arm,
-The end of the arm.

You "do" all languages huh? Maybe I should be impressed but I'm not.
Reeling off a list of programming languages (with one mis-spelled)
says little about depth of knowledge and corresponding skillsets. The
list does suggest most if not all of what you do involves procedural
programming.

>Only hackers (doctorates) work within my

Once again you make grand assumptions, your little circle is correct
and everyone else is wrong, wrong, wrong. AFA working with a bunch of
doctorates, what should be inferred? Both the top and bottom of a
graduating class get the same piece of paper. All the document means
is the course of study has been successfully completed, nothing more.

Re-read what you've written previously and consider the differences
between the "is a" and "has a" relationships.

>It takes too much time to keep correcting your errors in text, thinking,
>etc. Go play with someone else not ...
>

Like where I wrote the term dongle was coined in the early seventies
and existed before CAD applications? Oh wait you wrote that and I
pointed out that the generally-acknowledged first CAD application was
produced in the early sixties.

I'll give up and will concede that you are indeed a hack programmer.
Wear the title well.

3380. N6BT's "Vertical dipole"

Newsgroup: rec.radio.amateur.antenna
Date: 2010-08-05 18:33:25 UTC
From: Al Lorona <al_lorona@agilent.com>
Message-ID: <i3f07jbar1@speranza.aioe.org>
Source record: 8080

Anybody with experience with this antenna? It appears to be a quasi-vertical dipole with two "radials" attached to the bottom end and fed at the bottom. At least this appears to be the case; I could be wrong.

What issues arise when feeding a dipole at one end (the bottom in this case)? This can't be a truly balanced design, can it?

Al W6LX

Most likely, it is something similar to this:
http://www.earchi.org/pdf/ENDFED.pdf

Pick up a reasonable matchbox, or build your own, use with the above
80-10m. I'd be surprised if what he has warrants the expense.

i know better than whatever you think you understand of tesla's work,
and also have at least 60 years of research after he died to support
it. the first part of the arm is hottest, just like the center part
of the dipole that is not heated due to a bad connection... maybe you
make bad connections to dipoles, i don't!

3385. BNC Tribander for New TH-F6A

Newsgroup: rec.radio.amateur.antenna
Date: 2010-08-06 00:25:39 UTC
From: Patty <bonnypatty@gmail.com>
Message-ID: <ed765b96-24d3-4d73-8988-c36341fdec94@p22g2000pre.googlegroups.com>
Source record: 8085

I just got a TH-F6A and have been reading about the weakness of the SMA connector. I'm convinced I need to get an SMA-BNC adapter but I have found no BNC HT triband antennas. Are there any out there?

The Smiley 270A is a dual band 2M/440, but they claim it will also work on 440? Any experience with that?

Also, I have been thinking about Gulyas http://www.wa3hrl.com/smabnc/ SMA-BNC adapter in particular, but then I read this article http://osdir.com/ml/recreation.radio.hardware.kenwood.th-f6a/2008-01/msg00041.html It says: "To minimize the stress on the HT, I use the slick little adapter BGA-80 from Steve Gulyas. It uses a special o-ring arrangement that minimizes leverage against the SMA. Works pretty well. Its the best on performance, but too big to be attached to the HT when worn on the belt."

Does anyone have any experience with SMC-BNC adapters? Do any good ones allow you to attach your HT youir belt?

I'd really appreciate any suggestions you may have!

Patty

I hate to break in on private arguments, but Tesla was one of the
smartest people to ever walk this earth. Are You?
He invented Radio, but Marconi took the credit, using at least 6 of
Tesla's patents.
I can rant on Edison and Daguerre, but that gets long.
Some of you guys need a 'TRUE' history lesson.

Bill Baka, Listener only, since I rent these days.
Had a 1st Class Radiotelephone with Marine RADAR, P1-12-24966,
but gave it up some years back when they decided to do away with the
first class distinction.

Different numbers, but hard work to get anyway.

I was specifically responding to the part where it is claimed that Tesla
said EM is a myth. I feel quite safe, thanks.

But I wouldn't have debated alternating current motors with Tesla. No sir.

Just noticed the renter part.

I've been renting for 35 years and haven't been too seriously
constrained for most of it. And by not seriously constrained I mean 4
over 4 yagis at 25 and 37 feet with 1000 watts on 6m amongst other things.

If you work with your landlord you can often get permission for a lot.
And the right city helps, too.

Nikola Tesla wrote: " I showed that the universal medium is a gaseous body
in which only longitudinal pulses can be propagated, involving alternating
compressions and expansions similar to those produced by sound waves in the
air. Thus, a wireless transmitter does not propagate Hertz waves, which are
a myth, but sound waves in the ether, behaving in every respect like those
in the air, except that, owing to the great elastic force and extremely
small density of the medium, their speed is that of light."

Bill Baka wrote: "Some of you guys need a 'TRUE' history lesson."

There is also wrote that EM wrote Heaviside not Maxwell.
Maxwell's hypothesis was quite different. There were the molecullar magnetic
vortices. Inside the solenoid were millions of them. They rotate the
polarisation plane. What rotate it in Heaviside EM? Inside the solenoid is
the flux. Any rotation.
In our textbooks is wrote "whats a pity that to teaching was choosen
Heaviside not Ampere".
But Ampere is too sophisticated for students.

So, "I feel quite safe, thanks."

maybe in your 19th century text books, mine has plenty of Ampere in
it. you must remember, those guys were working things out as they
went along, their early writings were likely replaced by later ones
that changed with improved observations that disproved what they
thought at first. and then many things changed after the michaelson-
morley experiment dispelled the last believers in aether. so unless
you are studying things after that you are likely reading outdated and
well disproved early theories.

>i know better than whatever you think you understand of tesla's work,
and also have at least 60 years of research after he died to support
it. the first part of the arm is hottest, just like the center part
of the dipole that is not heated due to a bad connection... maybe you
make bad connections to dipoles, i don't!

Michaels answer was the best: "Aside from analysis, has anyone measured this
effect?

Is it to be expected in highly efficent antennas, or just inneficient
ones in which there is substantial heating already?

I have found that ice (hoar-frost) and rain do not disturbs radiating. But
the ice-water strongly. The ice-water is in a moment when the hoar-frost is
melting and in the pores is water (normally is air).

It is agreement with: " "In fact, most dipolar solids exhibit extremely
small dielectric losses since W tends to be extremely large. Water-free ice,
for example does not heat significantly under microwave irradiation."

I have found also that the temperature is measured for antennas for
annimals. The temperature rise must be below 15C. Of course they know the
details.

So no additional questions from me.

>
> Al W6LX

I've run plenty of base fed half waves, but never saw a need for
two lower elements.. You can't really call them radials in that case.
They have nothing to do with lowering ground loss.
But it's hard to tell, being I've never seen the antenna.
But if I were base feeding a half wave, I would not bother
with two lower elements spread apart. No real point in it.
The main difference in feeding at the base vs feeding in
the center is impedance. A much higher Z when base fed,
so you need a matching device. And for that I usually
prefer a single turn coil and a coax capacitor. Some have
called this a "gamma loop" matching device, which is
fairly close I suppose being as you tap the single turn
coil at the point of best match, much like the usual gamma
match. Truly balanced? Nope.. But that really doesn't
mean much. Even a center fed half wave can have common
mode problems. So it's not like that method of feeding cures
all feed line radiation problems.
They will both require decoupling sections for optimum
performance. But saying that, you can often run a half wave
with no real decoupling and have decent results.
It will vary to each installation.

Much of it is also available as streaming internet video.
Free video players are widely available. So, why invest
in the TVRO equiptment.

I like the Wi-Fi DX idea for the dish.

URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team. We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |
rec.radio.amateur.moderated |
rec.radio.amateur.space |

We are willing to provide any technical support necessary to get this
article updated and automatically posted again at a regular interval.
This would include establishing contact with the original maintainer for
any necessary permissions. We would prefer to seek a new, dedicated
maintainer at this time, rather than start auto-posting the original
article ourselves.

For more information about our newsgroup, see:
```

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to
rec-radio-info-request@panix.com.

MMX proved that no motionless solid ether. Such was necessary for the
transverse waves.

> so unless
you are studying things after that you are likely reading outdated and
well disproved early theories.

Now is the plasma physics: "Waves in plasmas can be classified as
electromagnetic or electrostatic according to whether or not there is an
oscillating magnetic field. Applying Faraday's law of induction to plane
waves, we find , implying that an electrostatic wave must be purely
longitudinal. An electromagnetic wave, in contrast, must have a transverse
component, but may also be partially longitudinal"

For Tesla ether is: "but sound waves in the ether, behaving in every respect
like those
> in the air, except that, owing to the great elastic force and extremely
> small density of the medium, their speed is that of light."

For Dirac it was an electrons see.

Now we know that in the electron see are the positive ions, So the plasma is
neutral.

As you see people step by step go ahead. Only you are standing in the
Heaviside's water (hydraulic analogy).

Tesla like Ampere are not in the teaching program.
Teaching programs are written by Ministry of Education.
Not all is in the teaching programs.

Up to now I have never seen opinion that Ampere and Tesla was wrong.
Remember that all scientists discard the Maxwell's hypothesis.

Heavisde made the EM.:
http://en.wikisource.org/wiki/Electromagnetic_effects_of_a_moving_charge
But he wrote: " I must, however, disagree with Prof. Thomson's assumption
that the motion must be irrotational. It would appear, by the above, that
this limitation is unnecessary."

The magnetic whirl was born. Teachers like it. They can write divrot H = 0.
It seems that you also like it.

they are not hard they are the basis of teaching modern
electromagnetics. Any introductory electromagnetics course uses their
stuff. if they are too hard for you that explains why you have all
those strange ideas, you are stuck 100 years ago with outdated over
simplified theories that have been disproved many times.

3402. what length for 1/2 or 5/8s UHF NMO whip

Newsgroup: rec.radio.amateur.antenna
Date: 2010-08-07 17:40:29 UTC
From: Robert Keeler <Robert.Keeler.6a38fe8@radiobanter.com>
Message-ID: <Robert.Keeler.6a38fe8@radiobanter.com>
Source record: 8003

I want to use an NMO whip for 460 UHF band. I know a 1/4 wave would be about 5.8 inches. can I cut it to be a 1/2 wave or 5/8s wave? if so what would the correct length be? this is a straight whip, no coil or spring. Thanks!

I think there has been some efforts to improve feedline decoupling
when feeding a .5wl antenna using radials. This may be such an
attempt.

I got an 3' long thin coax cable 'SMA to PL-259' adapter at Houston
Amateur Radio Supply. Good for mobile work, or via 3/4" dia. UHF lo-loss
coax from CableXperts.com up my 50'tower to Cushcraft 6/2/70cm beam, or
via RG213/X to the ArrowAntenna.com 146/440 J-pole on my roof. The
antennas are also a match on 224, but not much activity on that band.

Neither will work properly without matching. Without using a matching
device, you are limited to 1/4 wave, or 3/4 wave. And 3/4 wave is not
desirable as you start seeing higher angle lobes past .64 wave in
length. "5/8 wave"
If you have an NMO mount, and want to use a 5/8 wave, you need
one of the NMO mount 5/8 whips with the loading coil at the base.
A 1/2 wave will be high z, and require a matching device.
Without the proper matching, you are best off running the 1/4
wave whip.

Electromagnetics is a one form of Electrodynamics. The only form in teaching
program. The others is for selfteaching.
Here are the review: http://www.df.lth.se/~snorkelf/Longitudinal/node4.html

> Any introductory electromagnetics course uses their
stuff.

EM made by Heaviside is a simplification of electrodynamics. Teachers choose
it for teaching.

> if they are too hard for you that explains why you have all
those strange ideas, you are stuck 100 years ago with outdated over
simplified theories that have been disproved many times.

Ampere's longitudinal force was derived experimentally. So it cannot be
disproved.
Current elements (electrons) repel each others and thanks this the radio
works.

A 5/8 wave gives you the highest gain at low angles (which is what you
want). The length of the antenna is a '1/2 wave and a bit more'. The
loading coil at the base is essentially the rest of the length required
to make it electrically look like a 3/4 wave, so that it will have a low
input impedance, and be a good match.

Over a perfect ground plane, the 1/4 wave will have an impedance of
around 37.5 ohms, and the 5/8 wave around 50 ohms, so the 5/8 is
potentially a better match for 50 ohm coax. Also, the part of the
antenna which does most of the radiating (1/4 wave from the tip) will be
some 6" higher in the sky and, at 460MHz, if the antenna is mounted low
down, every inch of height above the ground counts! Despite this, in
many situations, you may not find much practical difference between a
1/4 and 5/8 wave.

I found only one practical difference. A 5/8 wave mag mount came undone
on the freeway. I've never had a 1/4 wave come off.

Your magmount obviously wasn't big enough. Was it one of those piddling
2" dia jobs? I've got a 6" limpet, and, with a 146Mhz 5/8 with the 3
turn 'spring' loading coil, there's no was that is going to come off at
any speed (regardless of headwind). Obviously, if the antenna is rigid,
there is more chance of levering it off.

just because he is in the books doesn't mean that everything he ever
wrote is correct. much of the early writings of all those guys was
wrong, it isn't until later when they had learned from their mistakes
that the final correct formulas of electromagnetics were agreed on.
for best results read modern textbooks, if you try to sort out all the
dead ends they went down from the early guesses you will need 100
years to figure it all out again.

3412. Built In Telescopic Antenna In "cheap" sw Portables ?

Newsgroup: rec.radio.amateur.antenna
Date: 2010-08-08 12:56:33 UTC
From: Bob <rgsros@notme.invalid>

Source record: 8012

Hello,

Not an antenna expert, so thought I'd ask here.
I've gotten some great info. from you folks in the past, which I really appreciate.

Will be buying a portable sw receiver for a gift.

Many of them seem to come with a built in telescopic antenna.
I guess the intent is to use fully extended, and vertically, although horiz. use also seems to be doable from the pictures, but would sure be awkward in a horiz. position I would think.

How "good" can one receive <30 MHz (and the normal fm broadcast bands) using one of these antenna vertically ?

Aren't most sw signals horiz. polarized, or, by the time they actually make it here, the polarization has become pretty much randomized ?

Will try with a "lon'wire" of course, but thought I'd ask re how good the built in antennas, vert. oriented, are as a general question.

BTW: anyone have any strong opinions on a good $ 250 max table top (preferred)or portable sw receiver for a very non-technical person ?
Would want it to have memories. SSB not necessary.

Thanks,
Bob

Hi Bob,

How good? Not very.

They will pull in the extremely powerful stations, but if you expected
to pick up a particular one, then you have every chance of failing.

>Aren't most sw signals horiz. polarized, or, by the time they actually
>make it here, the polarization has become pretty much randomized ?

Yes.

>Will try with a "lon'wire" of course, but thought I'd ask re how good
>the built in antennas, vert. oriented, are as a general question.

I have been a SWLer since the late 50s. Sometimes I was in the middle
of it, sometimes at the margins. Let me explain.

Here in Seattle, most of Europe is over the magnetic pole which makes
for miserable reception - others may have better experience. I have
had scant reception of Africa, outside of Radio South Africa (I was a
club member in the 60s). I had a very different experience with
Africa that I will describe in response to your next question below:

>BTW: anyone have any strong opinions on a good $ 250 max table top
>(preferred)or portable sw receiver for a very non-technical person ?
>Would want it to have memories. SSB not necessary.

I took a digital tuned SW radio (available from Radio Shack for $35)
to South Africa and casually tuned the bands there. With its whip
extended it was pretty boring, but it certainly had more signals than
I could hear from in Seattle. I came prepared for underwhelming
reception, however. Before expanding on this reception statement, I
would point out that "table top" radios are filled mostly with air so
that they can be big enough to call "table top." My $35 radio was the
size of a large paper back book. I have a $200 radio shack radio that
I suspect offers no better performance, but is too large for
intercontinental travel.

When we went to Africa, I brought along 30 feet of wire wrap wire with
an alligator clip on one end, and a quarter taped to the other. I
tossed the quarter over the rafters in our "hut" (built to 4 star
guest expectations) or into the canopy of the trees (the height was

never more than a dozen feet or so) and tuned in:

Arabic pgm.

I could have listened to so MUCH more, but I took the time to linger and try to pick up a call or interval signal.

There was more radio-activity on SW there, than on AM here; but I had to be there (a lot of this stuff was low power as you might imagine).

The bottom line is, cheap does pretty good if you know the limitations (the whip) and how to overcome them (a penny worth of wire). And, yes, it has memories (probably the simplest thing that could be done for cheap and digital).

More could be said.

wrong, it isn't until later when they had learned from their mistakes
that the final correct formulas of electromagnetics were agreed on.

I am not interesting in electromagnetics. It is the hydraulic analogy.

In Ampere electroDYNAMICS no magnetism.

>for best results read modern textbooks, if you try to sort out all the
dead ends they went down from the early guesses you will need 100
years to figure it all out again.

The XXI century will be the century of Ampere ElectroDYNAMICS. It is the
common opinion.

> --
> Ian

I realize all that, but he has no coil. Or at least he implied he didn't.
He was inquiring about using a 1/2 or 5/8 whip with no matching device,
which I don't think is too good an idea. Or at least he said no coil or springs in his post, so I assume no matching.
If he wants to run a 5/8 wave whip he will need to buy the coil that fits the NMO mount.
The 5/8 won't be potentially a better match for 50 ohm coax without the coil to tune to 3/4 wave.
I got the impression he wants to cut a longer whip and just stick it on the mount with no matching at all. Which was why I said 1/4 wave and 3/4 wave would be his only options and still have a decent match. And I don't recommend a 3/4 wave whip.
I've almost always seen an improvement using a 5/8 vs a 1/4 wave on 2 meters. A bit better range, and usually less picket fencing.
I would expect the same on UHF in most cases.
But if he wants to run a 5/8 whip, he is going to need the coil to go with it.

That's totally different than what I had in mind.
That is just a loaded vertical dipole with capacity hats on
each end. And looks to be center fed, not base fed.

Hey Cecil, good to see you! Wife asked if I had seen you about the
newsgroups, I will report your apparent good health to her.
That balun utilizes a ferrite rod anyway. A homebrew with a toroid
would be better anyway.

He does not mention a "50 ohm resistor" in his review document, not show it in his feedpoint picture.

Are you quite sure of what you say?

He does include load of 50+j500 in shunt with the feedpoint, presumably modelling the shunt coil... has that got you confused?

The next question is whether such a load is a good characterisation of the actual coil. The value of R seems rather high.

what good is a theory without magnetism. it obviously doesn't fit the
real world as we know it today. maybe it is your opinion, but its not
anywhere i have heard of. ampere's theory dates from almost 200 years
ago and was the predecessor of electromagnetics, so you seem to have
taken another step backwards, now you are almost 2 centuries out of
date.

Wouldn't that correspond to a Q of 10, which is pretty bad for a air
core coil. I'd say something like 30 or 100 would be more realistic
(unless it's wound with really fine wire)
(I don't have eznec, so I can't open the .ez file)

Beats me... I've never seen one of these antennas and am going only by the EZNEC model on that web site, as I said in my last post. Says that there's 50 + j500 at the feedpoint. That's a 50 ohm resistor in series with an inductor, isn't it? Or, as you say, a coil with a real low Q. Either way, it's an extremely lossy device that adversely affects the results. Try adjusting the R to a more reasonable value for an average coil and re-simulating in EZNEC and take a look at the result. KG4JJH has measured data in that review that definitely coincides with a 50 +j500 device at the feedpoint.

I opened the document in 4NEC2. Whilst my version of EZNEC cannot read
or write .NEC decks, 4NEC2 can read .EZ format.

If you look at the pic of the coil, a Qi of 10 seems very low.
Nevertheless, it doesn't consume much power.

I though about this while on the road this morning. Sometimes
enlightenment comes when there is not a keyboard to confuse things.

I assumed that he intended to model the shunt coil, and correctly
modelled it, but in fact his load is in series with the feedpoint...
so it hasn't captured the shunt coil.

Removing the load, and running the model gives a feedpoint Z of 16-
j500. A shunt coil with Qi around 100, and L around 29uH will
transform that to 50+jX. That coild has an equivalent shunt R of 120k,
so negligible power is lost in it.

I haven't looked closely at the model in all respects, but it seems to
do some crazy things that certainly give unrealistically low
efficiency.

Gravity force, electrostatic force and magnetic force are the real world for the most people. But not for scientists.
They know that in the space is the place for the one of them.
So step by step they decrease the number of them.
The first was Aepinus who proved that gravity and electrostatic are the same.
The last step was made by Ampere who build the artifical magnet - solenoid.
It means that magnetism is an ilussion like gravity. The all forces are electric.

> ampere's theory dates from almost 200 years
ago and was the predecessor of electromagnetics, so you seem to have
taken another step backwards, now you are almost 2 centuries out of

Heaviside was not scientists and he has taken another step backwards to Poisson's fluids.
He did not understand Maxwell and Stokes.

Teachers must be in "real world" and wait for the end of works on the Unification of gravity, electricity and magnetism (they are pending).

Hi John, tell the XYL that I'm doing as well as someone licensed in
1953 could be doing. :-) Someone used to post the r.r.a.* newsgroup
guidelines here, but I haven't seen it posted in quite a while.

it sure would be nice if gravity and electrostatics were the same
force, would make it easy to build antigravity device, just hook up a
van de graf generator and fly away!!! you really are digging up some
old and incorrect theories from long ago... keep digging and you'll

get back to the 4 basic elements, then you will know everything.

Moon dust fly away.
On the Earth the soap-bubble levitates if are charged.
Earth and Moon have the excess of electrons.

In the history are the reasons for which Maxwell did the hipothesis and and
why it was discarded.
Not as a whole. The math for solid body is in using. In a solid body are
stress and strains.

In the history no the school version by Heaviside. It is only in your "real
world" and in textbooks.

Well, that certainly allows "the little guy" to view the code and extract the important parameters, math and formulas so that they can construct their own specialized tools! Just a bit of understanding how math is defined by a computer language and you are good-to-go.

DANGER WILL ROBINSON!!! a 'bit of understanding' in this case could
lead to totally incorrect results. be sure you thoroughly understand
the limitations of the 'thin polygonal wire' model and any earth model
they are using. it is likely this will have lots of undocumented
limitations. also i worry about their claim of comparing to other
freeware results, do they only build models for comparison that are
well represented in both tools? and do they understand the

limitations of what they are comparing to?

One wonders why they converted Richmond's older code rather than NEC2.
Both are available as FORTRAN source. Even NEC4 source is readily
available these days, although not for free (so it wouldn't necessarily
meet their FLOSS objective.. I'm not sure.. they wouldn't be copying it,
they'd be converting it, by hand, to C++, and I think that would break
the "proprietary" link)

Maybe Richmond's code does insulation? or wires in a conductive medium?

the proprietaryness(is that a word?) or the copyright status may not be broken by changing language if the algorithms are claimed as the actual intellectual property... the code is just an implementation of it, no matter what the language. There would be no need to convert the fortran anyway, there are still fortran compilers available and you could call the fortran computations from any language gui front end. i'm doing a project like that now that calls old fortran, c, c++, or pascal computation modules from a new c# front end.

I would be really surprised if you could patent math formulas,
equations, etc. The software which uses them can, obviously, be
patented. Something with is "self-intuitive" or a law of nature just
can't be patented!

what is intuitive to you is a patented or copyrighted work from a
lawyer's point of view. while you can't patent or copyright maxwell's
equations you can patent or copyright a method of applying them to
come up with solutions to practical problems. these are common things
now in the software and business world, though some countries have
stopped issuing software patents and others are considering that move
also. but the copyright process is well ingrained in the software
world. So much so that there are specific copyright notices you can
use to specify that you DON'T want to stop anyone from using your
code, just so you don't get bothered by people asking all the time.

I don't think that's what's claimed by Lawrence Livermore Lab.. the code
is copyrighted, and the license agreement (I don't have it here in front
of me, so I'm working off memory) basically says you can't redistribute

the code. The algorithms have all been described elsewhere.

the code is just an implementation of
> it, no matter what the language. There would be no need to convert
> the fortran anyway, there are still fortran compilers available and
> you could call the fortran computations from any language gui front
> end. i'm doing a project like that now that calls old fortran, c, c+
> +, or pascal computation modules from a new c# front end.

I did wonder why the authors bothered to convert from FORTRAN to C++... but I think they did that as a separate activity, previously, for other reasons. There's a comment in their paper about not using automated translators, too (presumably to avoid any sort of claim that the output of the translator is somehow contaminated with the proprietaryness of the translator? Kind of like Intel copyrighting the assembler instruction mnemonics for the 8080, so Zilog had to use different ones)

Probably it's just a historical artifact.. when they started their development a while ago, they happened to start with the Richmond code, as opposed to the Burke and Poggio code.

I am not arguing the obvious, just that Tesla was a genius before his time. Edison had some creativity but mostly stole other people's inventions and made them work for commercially viable products.
He wanted to distribute DC power but Tesla wanted nothing to do with it so he became allied with Western House who knew that AC motors were the way to go. Since Edison went with D.C. and then found out it was only good at the local level he lost out. It took years but we can all see the effects by looking at those million volt transmission towers. I climbed one about 15 years ago and all I could hear was the crackling around me. Let Edison try to convert DC at that level.

I only commented on Tesla being a world smarter than Edison and did not intend to start an off topic war. P.S. Philo T. Farnsworth invented television, not RCA, who just ripped him off.

I had a 10 foot horizon to horizon Zenith dish and not only did I catch news anchors picking their noses but got a lot of shows a week before they were on regular TV. That was 1990 time frame, so much must have changed by now. I did pick up purely digital signals which were detectable as byte length dots and dashes (1's and 0's) but never recorded one. I have to wonder what those were. Now, in 2010 it may be a bit of an antique but I will bet there is still some interesting stuff going around.

You are obviously not renting from Herr Commandant Earl Kennedy. He
doesn't allow shit except for maybe a long wire run through the trees.
If he can see it, he says take it down. I can't wait to move to a house
that is farther out and he doesn't own.

I didn't start this to be a flame war, but I should have known.
As for really high magnetic fields they have levitated a mouse in the
lab with about 5 Teslas interacting with the water in his body.

HVDC distribution systems over long distances are not that uncommon.

http://en.wikipedia.org/wiki/High-voltage_direct_current

The Pacific DC Intertie from Celilo, Oregon to Sylmar, California is just
under 2,000 km long and runs at .5 MV.

> Bill Baka

well, actually edison was right... and many long distance transmission lines today are DC at up to +/- 600kv, that will put a crackle in your snap and pop! There are also places where interconnects between major AC systems are done using back to back AC/DC converters so that the systems can be isolated due to voltage or frequency control issues. don't count out large dc motors either, our submarines have been using them forever... even nuclear subs have dc propulsion systems. All solar panels start as DC, as are most of the storage systems for them, and don't forget plugin hybrid or all electric vehicles, most all of them are dc powered. There is also a new move to use DC distribution in large data centers to reduce heat from transformers and simplify backup power systems. most subway systems and electric rail i believe are also dc powered. and believe it or not, there was still a block in nyc that was provided with dc by ConEd until 2007, and as i understand it they had to provide custom rectifiers for some equipment that was still in use so they could retire the rest of that system.

I never seen this as a problem or a road block. You are simply a matter
of all the knowledge you have picked up from others along the way, most
likely, a large portion of this came from copyrighted materials.
Indeed, if I read a copyrighted book, then turn around and write a book,
containing all I have read, I have done no wrong; If I copied the work,
I am.

When it comes to math, removed from other works, it is exactly the same.
You would have to be an idiot to do it in such a way as to cause problems.

This is all so self-apparent, it always puzzles me when I am brought to
putting the concept(s) to text, or even spoken speech!

" Due to the space charge formed around the conductors, an HVDC system may have about half the loss per unit length of a high voltage AC system carrying the same amount of power. With monopolar transmission the choice of polarity of the energized conductor leads to a degree of control over the corona discharge. In particular, the polarity of the ions emitted can be controlled, which may have an environmental impact on particulate condensation. (particles of different polarities have a different mean-free path.) Negative coronas generate considerably more ozone than positive coronas,"

But what it works in your antennas.

FORTRAN is pretty much a dead language, although you will find strong argument to that statement in some math circles. While I do agree that language makes little difference to software engineers, most being fluent in many/multiple languages, a C translation just keeps the code, more, up-to-date.

And, none of the above is of any real importance, other than complete, or even substantial fragments of, programs can be copyrighted. But, I am sure there are millions of "for statements", etc. in code that are exact duplicates of some found in Microsoft Windows, etc. To claim that the truths of mathematics is patentable is just stoopid.

However, all that said, there are such things as "encoder algorithms", for an example, and such, which are so narrow and contain such an exact and specific set of math instructions to execute and obtain reproducible results from, that the validity for a patent is quite obvious. However, as has been demonstrated, for any patented algorithm which has yet been created, a freeware solution which is either so close in effectiveness as to make it a moot point, or even greater in effectiveness--an example is MP3 format (patented) as relates to Ogg Vorbis format (public domain.)

The future where patents cause real road blocks in software development, or even "hoops to be jumped through", is still in software engineers' future.

don't bet on it. microsoft just had to remove a major feature from
word because of patent infringement. and there are lots of cases
where companies have to buy rights to use patented features before

they can release their products, compression algorithms are just one of many things that have been patented. even the cursor and the mouse have patents. fortunately most of my work is using standard tools that come with distribution licenses, and the stuff i develop that is unique is from our own research programs so we obviously own the rights. but if i find a free tool that has something that will make my job much easier i have to submit the license to our software quality and then maybe legal offices to be sure we can use it without infringing. you know those long license statements that no one ever reads before installing something?? most of them unfortunately make sense to me now.

FORTRAN is far from dead in applications processing massive arrays (just about any finite element program). For instance, I'd venture that most weather prediction codes are in FORTRAN (MM5, which is a widely used mesoscale modeling code, is in FORTRAN, as is WRF), as are a lot of structural analysis (e.g. NASTRAN is in FORTRAN), and virtually ALL electromagnetics codes.

FORTRAN is hard to beat when it comes to specifying array operations, and such. Running gridded models doesn't require much in the way of pointers or string manipulation, which are admittedly a pain in older FORTRANs (pre FORTRAN-90 or FORTRAN-77). FORTRAN also has an intrinsic Complex type which is nice.

Compilers for numerical analysis applications (e.g. those weather grid models) for FORTRAN are highly optimized, too. There's also nifty tools like FLIC (FORTRAN Loop and Index Converter)

There's even new versions of FORTRAN coming out.

Unless you need compatibility and interoperability. Sure, there are
non-patented communications coding schemes like LDPC that give better
performance than, say, Turbo codes (patented), but if you need to build
a radio that interoperates with a radio using Turbo codes, you're pretty
well stuck.

All the various high performance low bit rate voice codecs have similar
issues. All the "good" ones are patented, as well as most of the "not
quite so good", and the patents are broad enough that you would have a
tough time designing around them. (which is actually, I think, how it
should be.. patents *should* be for fairly general conceptual leaps, not
for some fiddly little detail that's different.. that's what "design
patents" are about)

Fortunately, the patents *will* expire. Unlike copyright, which has an
ever longer tail.

>
> The future where patents cause real road blocks in software development,
> or even "hoops to be jumped through", is still in software engineers'

I don't think so. It's here now, especially if you consider advanced
signal processing or protocol handling in software. The software is just
the means by which the invention is realized, and it's no different than
doing it with discrete hardware components. While raw "algorithms" and
"math" can't be patented, a clever and efficient implementation
technique certainly can be.

I though about this while on the road this morning. Sometimes
enlightenment comes when there is not a keyboard to confuse things.

I assumed that he intended to model the shunt coil, and correctly
modelled it, but in fact his load is in series with the feedpoint...
so it hasn't captured the shunt coil.

Removing the load, and running the model gives a feedpoint Z of 16-
j500. A shunt coil with Qi around 100, and L around 29uH will
transform that to 50+jX. That coild has an equivalent shunt R of 120k,
so negligible power is lost in it.

I haven't looked closely at the model in all respects, but it seems to
do some crazy things that certainly give unrealistically low
efficiency.

Owen

These days, I choose to program, almost exclusively, in assembly and C/C+/C++ (all C looks the same to someone writing in it.) If someone hands me a FORTRAN coded work, I can read it, but it tends to look like a mess to me. I simply run it though a source translator/optimizer and I have C code. When I am done, if they requested the result in FORTRAN, I run it back through the translator in reverse. C is simply a universal language which has the most favor with engineers and which has become the industry standard. Like I said, arguing language is a moot point ...

> FORTRAN is hard to beat when it comes to specifying array operations,

FORTRAN is not "hard to beat" at anything. Assembly instructions are the only "real code" which a processor understands, it is the binary language of processing units. There is not a computer language in existence which does not translate to assembly before execution. FORTRAN and C only differ in semantics. While FORTRAN was an attempt to make the language more readable in translation, C is an attempt to make the language more efficient in translation. The goals of the two languages are not exact.

> Compilers for numerical analysis applications (e.g. those weather grid
> models) for FORTRAN are highly optimized, too. There's also nifty tools

Microsoft stole Java from Sun and attempted to make it, its' own.
Microsoft has a long history of this. The type(s) of individual(s) who
do such seem to infiltrate large corporations in large numbers.
However, really a moot point to the direction in which this conversation
first started ...

>> >> even the cursor and the mouse have patents.

Yeah, as if someone grasping at straws and thinking that "just owning a
patent", in someway, is some kind of status symbol ... something which
fails to impress anyone worth impressing.

>> fortunately most of my work is using standard tools
> that come with distribution licenses, and the stuff i develop that is

Yeah, most people double check their work(s) and have others do so, if
available ...

Frankly, I find that amazing, indeed, it implies insanity to me.

Why anyone would allow a thesis to be done which would favor a particular language defies rationality. As, language is only a device for the implementation of truths, ideas, algorithms and laws. It is the underlying structure of math and logic which are the only important points. To express these in a form speaking to computer engineers, a "language" such as pseudo-code would be the logical choice. To do any different simply implies there are interests at work other than pure science.

Are you sure a FORTRAN compiler/developer with financial interests did not back this academic venture? ROFLOL

> going around.

There's a lot of sports programming available in the clear, both
analog and digital. On a far west C-band satellite (135-degrees West,
I think) I could still get the Alaska network digital feeds until
recently in San Diego. (I took down my 10-foot C-band dish a few
years ago, so my knowledge is getting stale.)

Much info is available on skyvision.com and satelliteguys.us . Also
see lyngsat.com and sadoun.com . The science of cataloging what's
available is not perfected, as the programmers don't care that we know
what's on -- unless we're paying customers. :-(

The fun is building the gear, especially antennas and mounts. I hand-
built a geometrically-correct polar mount out of the pipe from a
DirecTV wall mount and an ordinary TV antenna rotor. It tracked the
arc perfectly for a small Ku dish. I still have it and I'll post a
picture if anybody wants to see it.

I hope this helps.

Your antenna is a high voltage AC system.
The loss is a loss of electrons.
Try to measure it.

well, that just blew any credibility you had with me. c+ is a joke,
c# is real, and no, all flavors of c don't look the same! far from
it, someone who knows c would be lost doing c++ or c#.

and yes, there is a huge fortran codebase out there in scientific and
engineering circles. many of the largest modeling packages use
fortran for at least the backend, even if the frontend has been
rewritten in a more gui friendly language.

antennas work just fine without a ground. how do they work in
airplanes? how about spacecraft? yes, i know, you like plasmas that
provide the free electrons... but you are wrong. take a transmitter,
encase it in rubber, put it in a vacuum chamber and pump out all the
air, and you will still receive it.

See at the fig. 1: http://amasci.com/tesla/tmistk.html
Can it work without Gnd?

You can use a chassis.
Transmitter is only a oscillating pump. Such must has a tank.

Gibberish and nonsense based on ancient crap.

Connect an RF source through a transformer with the secondary connected to
a dipole and hang it from a balloon; works fine and no ground or chassis.

>(can be both better or worse).

Additionally the dipole may be a better match for 75 ohms than 50
depending on height and surrounding conditions.
I used 3/4" 75 ohm coax for low loss, long runs for years with no
problems and never paid attention to length.

OTOH at times using a commercial multi band vertical I had to play
with the 50 ohm coax length even when the antenna was a good match.

Stateside the F to UHF connectors are relatively inexpensive and
common. They may not be the best quality but work well indoors.

Welll... I had a number of HTs using BNCs over the years. The ones
that were used a lot in general needed the Chassis connector changed
once a year. I've yet to have to change an SMA.

That should be fine. See my notes at
http://vk1od.net/transmissionline/RG6/index.htm . See Fig 2, RG6 should
handle over 1kW continuous at 14MHz at unity VSWR, over 500W at 2:1
VSWR.

The article also shows a BNC connector option which IMHO is superior to
F connectors.

An alternative method of matching is to shorten the vertical a little
from a quarter wave, and use a shunt s/c stub. See
http://vk1od.net/transmissionline/QWVmatch/QWVmatch.htm for a
description of this and another method of matching.

OK. I dug it out and I'll snap some pix later.

Questions: Do you understand the geometry involved in a polar mount?
How about the concept of declination, whereby you compensate for the
fact that you are not on the Equator? When I bought my 10-foot dish
(1986) it came with instructions that included a table of declination
vs. latitude and a corresponding adjustment scale on the mount
itself. With a do-it-yourself dish, you have to "do it yourself." hi
hi.

I ask because the web has a number of tutorials on the subject of backyard dishes. If you don't already have the knowledge, you may wish to search now. Not a big deal, but if you fail to apply the correction, you can't track the arc faithfully.

On the side: We are discussing herein a polar mount, whose operation adjusts azimuth and elevation simultaneously. There is also an AZ-EL mount that permits you to manually aim at each satellite, based on pointing info derived for your location. Simpler, but not much fun to build.

PDP8 assy? 12 bit machine wasn't it? (didn't look it up, not cheating)

I rebuilt one after someone plugged the TTY card into the bus. You may remember that none of the cards were keyed. Loop current voltage hits the bus, oops. Lots of RTL and DTL to replace.

yeah, pdp8 was 12 bit, everything in octal instead of hex. i did a lot of 6809 stuff on a ratshack coco machine, amazing what you could make that box do once you got inside it. had one doing fax, rtty, 4 channel music synthesizer, and running a dialup bulletin board even before aol started sending out floppies. and i built an 8080 based desktop computer from scratch in 1977, all of 2k of ram and a hex keypad to load the programs from manually or from cassette tapes!

I ran OS/9 on my CoCo. I had dual 5 1/4 inch drives, woohoo! Also got
a couple things published in Hot CoCo if you remember that mag.

OS/9 was great. Developed by Motorola as a micro based Unix type O/S.
I heard it was parallel developed with the 6809 chip with feedback
between the 2 teams. It was very fast and very small. Kicked the IBM
PC's butt with one fifth the clock speed. As you may know, the 6809 was
about as much 16 bit as it was 8, which was probably part of the reason why.

And I still have all of the bits. Haven't fired them up in maybe 15
years. I wonder if the disks will still read.

Anyone else would have asked who Mr. Ostrom is - or wait for Mr.
Ostrom to indignantly reply (and he did).

Start thinking. The dipole is a very long wire. The electrons are emitted
from the ends only. The rest of the wire is the chassis.
The very short dipole (0.05 wavelengh) should not work fine without ground.

All antennas are the same:

"In conventional ICP (or TCP) reactors, a rf power is inductively coupled to
an antenna placed outside a plasma vessel. Such an external coupling system
is known to have several disadvantages. In order to avoid these
disadvantages, a new internal coupling system has been developed in which a
bare metal antenna is directly immersed in a plasma, thus forming a full
metal reactor. This is accomplished by generating magnetic field lines
around an antenna conductor, which effectively suppress the electron loss at
the antenna and hence suppress the anomalous rise of plasma potential.
Magnetic fields near the antenna are formed by superposing a dc current on a
rf current along the antenna. This type of ICP enables rf discharges at
rather low pressures such as ?3&#65533;10-4 Torr due to the magnetron effect. Other
characteristics of internal metal antennas are also discussed".

"the electron loss" and "the anomalous rise of plasma potential." apply to
all antennas.

no they don't. that discusses a rather unique situation of an antenna
in a very low pressure plasma. another case where google supplied
irrelevant information because of your ignorance of the actual physics
involved.

oh yes, i remember hot coco... at one point i had 4 floppies and extra
ram extension on my coco. that was when i was using it as a bbs.
finally turned it into a repeater controller in the mid 80's.

Babbling nonsense contradicted by about a hundred years of empirical
observation.

only if the thesis didn't care about the exact implementation, but did
depend on the algorithm. if the code were just a tool used to crunch
data, which is what it sounded like in that part of the discussion,
then the code itself may not even be part of the thesis, just the
results of crunching.

Owen Duffy wrote:

> The article also shows a BNC connector option which IMHO is superior to
> F connectors.

BNC compression connectors are available. They are much harder to install properly than F connectors, but once you "get the hang of it", they work fine and are sturdy. BNC to UHF adaptors are also available, and the ones I have seen are better quality than the F to UHF ones.

I don't know if they are as water resistant as the F connectors designed for outdoor use, but UHF (PL-259) connectors are in comparison sponges, so if you are used to them, you should be able to deal with BNC connectors.

Note that there are different connectors for RG-59, RG-6 (not quad shield) and RG-6 quad shield, and they can not be used on cables they are not designed for. Either they don't fit on properly and don't make connections, or fall off. :-(

You can buy a package of compression 50 BNC connectors and the appropriate tool with international postage for about $50 on eBay.

There are three kinds of compression connectors I have seen so far.
One is a one piece solid connector, which when compressed, the back end folds into itself (think of a metal accordian). The second is made from two pieces fitted together, and when you compress it, the part in the back is compressed into the front.

Both work well, and if you get the trimming right, will fit well. I found on the two piece verisions I have, the center conductor has to be trimmed to 3mm. 4 or more and they fall off. :-(

Note that when I say two piece, when you get them they are both one piece and can not be separated. It's just obvious that not counting the ring, they were made from one or two pieces.

There also is a third kind I have so far only seen in F connectors where the front pushes into the back. I tried many in all sorts of ways and cables, and either end up with it falling off, or making a solid fitting but no contact to the shield (ground). :-(

Any advice on how to get them to work would be appriceated. I still have around 30 of them.

Geoff.

Hello,

We would like to thank you all very much for your kind attention you paid on our work; especially, since the appearance of vemsa3d 1.1 announcement is still delayed for 5th day, as we will like to reveal, in some other e-mailing ham antenna lists commercially moderated outside the USENET. Well, we tried to collect all of your remarks which are strictly related to vemsa3d, and here are our due answers:

1
The reason for which the code was translated from FORTRAN to C++ was to establish a uniform language environment, most appropriate to be a graphics oriented one, from the scratch.

2
The reason for which the transform was made line-by-line was to fully control the reliability of this transformation.

3
The reason for which we used RichWire -that is our fully analysed and then revised Richmond's FORTRAN code- beyond those reasons mentioned in our page limited paper, as it is already pointed out by Jim Lux, was that NASA does not put any restriction in its public domain code on the number of modeling current modes, that is on its modelling capabilities.

4
The reason for which we focused and concluded with that particular horn comparison example between 4nec2 and vemsa3d was to emphasize that very important restriction on the limited modelling capabilities even with physically short electromagnetic objects like that horn for which we exceeded the maximum number of 4NEC2 permitted dipole mode currents by a factor of about 4, that is up to almost 5,500+ dipole current modes.

5
Finally, the reason for which we carried out this overall tedious, much time-consuming, work was to stop discouraging "the little men" like us -not only the guys of John Smith but the dolls too- from being involved with the electromagnetics modeling interiors, on which, some other people, had been artificiallly put knowledge barriers. From now on, as we hope, there is no self-excuse for no one to hesitate in trying his/her forces on this, most demanding, most challenging,

multi-discipline field.

Well, after the above clarifications, we don't see any other, either straight or impled, question among your very welcomed indeed comments, which is strictly related with vemsa3d and remains unanswered. Anyway, if there is indeed any point that was missed our attention and you are really interested to be cleared, please definitely put that to try to answer it too.

if you can't code it in a 'real' language how would you code it in a
pseudo code? that just doesn't make sense. the whole purpose of
pseudo code is to help work out logic and program structure at a high
level. it wouldn't be much good if you couldn't break it down into
actual code in the end.

Your interpretation of pseudo code seems much broader than mine. I view pseudo code as a non-verbal means to describe the nuts and bolts of an implementation. I don't see pseudo code having the ability to describe design patterns, even basic procedural patterns such as inheritance, polymorphism and encapsulation. Pseudo code just isn't abstract enough and doesn't scale well enough to communicate larger, more general concepts, principles and ideas.

A design pattern might call for a collection of references to objects where pseudo code would use an array of pointers. Abstractly they are the same but while a pointer is a reference, a reference per se does not have to describe an object's location in memory. A reference could be something as simple as an index into an array. It's a subtle difference but most meaningful. In this example the design pattern can be implemented in C# while the pseudo code presents a stumbling block.

Then again at certain levels of abstraction, design patterns might be described as being pseudo code. Design patterns are very useful in revealing what public properties and methods types will require without drilling down to implementation specifics.

>it wouldn't be much good if you couldn't break it down into
>actual code in the end.

Design patterns can do this nicely for OO languages. I can't speak for FORTRAN as I haven't had occasion to use that language in almost forty years. Still it seems a FORTRAN flow chart would fall somewhere between design patterns and pseudo code. A flow chart does describe a specific design without specifying implementation details.

You're welcome. The OP said his dish was 2.5m; how big is yours? Or do you have one yet?

I had a 2m solid dish for a few years (unused) and finally gave it away. That thing was heavy. I never had the whole mount for it -- just a tripod frame off the back of the dish -- so I can't offer any direct suggestions. One idea, if you have a communications company nearby, like the area cable-tv provider, maybe a friendly tech will let you into their yard, where you can examine how their dishes mount. Just a thought.

My other dish, a ten-foot mesh unit with which I watched premium programs for fifteen years, is now in EME service a few miles from here. Are you thinking EME?

I have built a 4 element Delta loop for 20/17/15/12/10 meters and it has full gain for each band. I have been working with this antenna for some 20 years now and have got it working pretty good. If anyone wants to see my figures, go to rgantennaparts.com to see information about this great antenna. I am presently building a 7 band 2 element rotatable delta loop. This antenna has the 40/30 bands included. The figures for gain, back to front ratio and matching impedance are there. This antenna has wire supported by fibreglass poles instead of the regular aluminum elements.

The connector itself on the TH-F6A isn't particularly strong, but there is a raised ridge around it on the case that the supplied rubber duck rests on to take the mechanical loads. If you're putting a different antenna on, what you probably want to do is what a colleague of mine did: find a nylon bushing that's just the right height to support the bending load of the SMA/BNC adapter on that same ridge. Rummaging at the local hardware store he found one that required only a tiny bit of sanding to make it work.

Then, he did the usual "two right angle BNC adapters" to further relieve the stress loads.

3525. Measuring Balun effectiveness

Newsgroup: rec.radio.amateur.antenna

I have some professional Fischer current probes (clamp-on current
transformers).

For a simple dipole, balun, 50 ohm coax feed system...
It seems to be that I can simply clamp one on the rig side of the
balun, and see how much current is flowing and compare it to antenna
current. I can clamp it on either, or each antenna leg near the feed
point to measure antenna current.

It'd also be interesting to probe several points along the feed line.

Anyone see anythhing wrong with this reasoning?

>Anyone see anythhing wrong with this reasoning?

Hi Steve,

You will have the length of the line leading to the probe in the radiation field and it will disturb the transmission line coupling to that same field, changing the current characteristics. At some point, it won't matter, at other points it may matter considerably - the trick is knowing one point from the other. What will be happening is that you will force a common mode into a balanced circuit, or will be further unbalancing an already unbalanced load with that long length of line.

In other words, it will be a joker in the deck unless you choke that line too.

The question then comes to this: Why are you doing this? Is this some form of classroom experiment with what was called Lecher lines? Measuring SWR? If so, you might find that you are pushing the current node along the line (like a bead on a string) as you slide the probe. At some point the node will pop back to its original position and if you are trying to plot current points, they will exhibit a curiously distorted shape. This can occur through overcoupling the probe to the line.

> It'd also be interesting to probe several points along the feed line.

You realise of course that the common mode current is almost certainly a standing wave, and meaasurement at a single point is not a reliable way to characterise a standing wave.

I know that this is not consistent with the widely held view that a common mode choke creates a demarcation point where common mode current can flow on one side and not the other.

This is the pitch for the very popular Carolina Windom which advertisers and promoters claim leverages the radiation from the vertical feedline section on one side of the "isolator" but there is no undesirable common mode current on the tx side of the "isolator".

>
> Anyone see anythhing wrong with this reasoning?

To assess effectiveness, don't you first need to take inventory of what it is supposed to do, then assess its performance against those criteria? Have you a list of expected benefits?

There are a lot of flawed common mode current measurment articles around, and even some commercial instruments that seem not cognizant of the fact the line currents are complex quantities (eg at least one MFJ 'instrument'). Most reports I have seen of "I have common mode current 20dB down" speak more of the reporters lack of knowledge of the problem and measurment technology than 'clean' status.

If for instance, one of your benefits was reduction of receive noise level due to proximity of common mode conductors with household noise sources, then your current test is not likely to be a good measure of that outcome.

If the objective is EMC improvement on tx, then isn't the best test observation of interference to yours and your neighbors TV, HiFi, computer, telephone etc? These effects usually incorporate a threshold effect, and if field strengths are below threshold, your home free.

I am not familiar with the equipment you have, so ask the question, can you measure the phenomena without significantly disturbing it? If I was designing a common mode current probe, I would think of a small self contained thing with a panel DMM readout, battery powered, and that could

be clamped to a conductor and read remotely with a telescope. Anything with substantial length of conductors is likely to be a problem.

Owen

Ideally, the high-impedance "isolator" causes a reflection of the
forward common-mode wave back toward the antenna. This ideally results
in a current node (minimum) at the "isolator" and ideally confines the
common-mode standing wave to the feedline between the "isolator" and
the antenna. That's the theory behind the Carolina Windom. How it
performs in reality is another question.

It should be easy to measure the common-mode current at a few points
between the isolator and the antenna and at a few points between the
isolator and the shack to determine just how effective the Carolina
Windom "isolator" really is. It should also be possible to model the
situation with EZNEC - no, not a perfect model, just close enough to
observe the effect of the "Isolator".

Does anyone know the choking impedance for the Carolina Windom
"isolator" over the spec'ed frequency range?

A strategy that is used in antenna research with bolometers is to use wires with an impedance of 377 ohms/square so they "look" like free space and don't perturb the field. I haven't seen these as a commercial item, so I suspect that they are fabricated by the researcher: perhaps by cutting from sheets of so called space cloth or paper (which has the required sheet resistance)

Check out the work by Bolomey, et al., with measuring fields with "modulated scattering probes" (put a small dipole in the field with a diode in it that you can turn on and off with a DC bias, supplied by resistive lines)

The idea is to increase the radiation resistance, not to decrease it, so
has to increase efficiency.
>
>>
>> The 8 radials will be 4 feet long with loses of aprox 5 ohms, so
>> efficiency will be near 94%.
>
> This isn't entirely clear to me.
>
> Owen

If I define radiation efficiency as:

Rr/(Rr+Rl)

where Rr; radiation resistance
and Rl: loss resistance

and take Rl=5 ohms for 8 radials of 8 feet each

For a 25ï¿½ length radiator: 36/(36+5) = 88%
For a 32ï¿½ length radiator: 100/(100+5) = 95%

Losses are reduced from 12% to 5% by only adding 5 feet to the 20 meter
vertical quarter wave antenna and with a 75 ohm coax of 1,25 wavelength
I can get a perfect match to a 50 ohm output impedance transmitter.

The 8 radial can be as short as 4 feet long for the same results.
I came to these results from R. J. Edwards (G4FGQ) program ENDFEED.EXE
It's interesting to note, that radial longer than 1.3m (4 feet), always
increase earth looses.

The complete modeling results can be seen at:

Dear Mr. Miller,

VEMSA3D can not work differently, because it is based
on the same theoretical method as NEC does, that is on
the Method of Moments.

However, since each of these numerical applications use
a different basis of the current function space and since
their corresponding computer programs use unavoidably
finite linear combinations of them, in general, they
produce different results.

To be specific, the two bases details are included in the
following:

VEMSA3D current basis:
J. H. Rischmond, Radiation and Scattering by Thin-Wire
Structues in the Complex Freqeuncy Domain, (15), p.6
http://tinyurl.com/24zwycy

NEC current basis:
G. J. Burke, A. G. Poggio
Numerical Electromagnetics Code - Method of Moments
Equation (20), p. 11
http://www.si-list.net/NEC_Archives/nec2prt1.pdf

Regards,

Petros Zimourtopoulos

The model sensitivity to radial length suggests that the radials are modelled as short transmission line immersed in a lossy medium, in which case, the assumptions about soil conductivity and permittivity are very important to the model accuracy. It is unlikely though that shallow buried radials are very consistent in behaviour due to the effects of rainfall.

It would be interesting to measure the antenna and compare it with your model predictions.

Owen

Can you quantify further or explain the nature of thes "different results?"

Are there certain classes of antennas for which VEMSA3D might produce more
accurate results than NEC?

Thanks!

I use a lot of compression F connectors that are truly 2 pieces with
the back piece being pressed into the front.
The front part has an extension that *just* fits over the foil and
under the braid and jacket. The back part is a snug fit on the jacket.
When the back is pressed into the front the forward part with a soft
plastic gasket compresses down on the jacket and braid giving a strong
connection to the braid and foil. The center of the coax (RG6) forms
the center pin of the connector. I just leave it long until after the
connector is installed. Then trim it off about 1/16th inch in front of
the connector. You can go a good 1/8th inch or cut it flush so there
is lots of leeway.

I use a commercial pair of pliers made for installing these, but it
would be fairly easy to make up a set of pliers if need be.

Hacksaw, the tool of professionals. Boltcutters work on the cheap SS
whips, but a good spring steel whip can divit bolt cutters. A carbide
cutting disk in a dremel tool or grinder is another option.

For those "tool challenged" a hacksaw blade with several wraps of duct
tape around one end will work.

|
| - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -

Well, I can try. These numerically different results are due
to the different coupling -reaction, or impedance- between two
```

current distributions for which different function -expression,
type, formula, or equation- is used to describe them in each
one of the two applications, VEMSA3D and NEC.

You are welcome!

VEMSA3D is a thin-wire polygonal modeler in "free space".
Therefore, it has to "exactly" predict or justify the
characteristics of any thin-wire antenna. For this class of
antennas VEMSA3D can be certainly compared with NEC. Anyhow,
this comparison can only be indirect: you have to build and
measure the specific thin-wire antenna first and then to
overlay the results of both applications upon the
measurements. But since this kind of knowledge is definitely
a posteriori, you can try a comparison of both applications
for *any* class of antennas. Here, only the advertisement
builds knowledge a priori; but usually this is followed by
a deep disillusionment.

If you're talking a good quality whip, like one made from 6140, you will ruin your pliers or even the best bolt cutters you can find. They may work on cheap whips, like the ones on discount store CB antennas, but not on a good quality whip. And it seems that some of the 'thinner' whips are tougher than the thicker whips.

Notch it with a file or an impregnated fiberglass wheel on a rotary tool, than bend it sharply and it should snap off clean. The harder the steel and the more difficult it is to cut, it seems the more brittle it gets, and the easier it is to snap.

Hello, again, JS!

For MMANA-GAL, I just took a look at:
http://mmhamsoft.amateur-radio.ca/pages/mmana-gal.php

where you can also read that, according to its developers,
this application is a descendant of MININEC, that is of NEC.
Therefore, there is no need to add nothing more on what already
written in some previous articles of this thread about VEMSA3D
and NEC.

Furthermore, I also just took a look at:
http://dl2kq.de/promm/

where you can read too that its developers clearly exhibit its
license and capabilities limitations. Therefore, there is also
no need to add nothing more on what they already wrote -not to
mention what it is lengthy said about software pattents and usage
restrictions in this tread.

Finally, the accuracy issue is also has been exhausted in
yesterday article:

| Sent.....: Sunday, August 22, 2010 9:38 PM
| Newsgroups: sci.physics.electromag,rec.radio.amateur.antenna
| Subject...: Re: vemsa3d 1.1 - a floss visual em simulator for
| 3d antennas
| From.....: pez@grnet.gr

so I have also nothing to add.

Well, after all, it seems that we only forgot to mention the name of that elephant in the room -perhpas because its advantageous name is /F/L/O/S/S/.

Best regards,

pez

Yes, the free, as in free beer is one great advantage, but an advantage not all will be able to take advantage of. Since MMANA-GAL and EZNEC have visual interfaces so similar, being able to use one is effectively being able to immediately use the other. The learning curve into your interface takes just a bit longer ... but, as you say, the availability of the source makes it highly desirable to at least one group.

Thanks for the swift reply,
JS

3552. Antenna analyzers, opinions please...

Antenna Newsgroup Denizens:

Apart from the professional 'lab grade' (and undoubtedly very expensive) devices made by the likes of Agilent, there are on the amateur market several antenna analyzers that are more reasonably priced.

I'm currently considering the purchase of such a device, and so...

I'm interested in hearing opinions, pro-con arguments, and/or receiving pointers to reviews of such devices.

All thoughts and comments will be appreciated, unbiased or not.

Thanks!

I have only one comment which applies to most if not all of the amateur level products, as well as a very high quality HP impedance meter I used years ago.

I live about 15 miles from hilltops where the local AM, FM, and TV broadcast towers are. The signals from those stations are strong enough to overwhelm the broad bandwidth detection circuitry in the analyzers (and HP vector impedance meter) I've used, resulting in meaningless readings when connected to an antenna. I find that I grab my MFJ antenna analyzer for a host of jobs like measuring a ferrite core impedance, checking the length of a piece of coax, and so forth. But for me it's just about useless for the job of analyzing actual antennas. When I need to measure antenna impedance I dust off an old GR bridge and use a portable receiver for the detector in order to reject the strong ambient signals.

Of course this isn't a problem for everyone, but it sure is for me and I don't think my situation is unusual for an urban environment. I've had to put common mode chokes on my thermometer thermocouple wire, my light meter connecting wire, scope leads, and even in audio circuitry to keep the RF out. But even one strong local station might be enough to upset a typical antenna analyzer.

I've used Autek Research "RF" and "VHF" Analysts for some time and
they've served my purposes for antennas and testing.

Also Heathkit, Diamond (VHF-UHF) and Daiwa power output & SWR meters
in-line on coax.

Not so important if one uses a Tansmatch or tuner with them built-in.

Roy:

Thanks for your input on the effects of interference from other transmitters, especially BC transmitters, point well taken.

I suppose one might add some kind of carefully designed passive filtering to the devices to 'notch' out offending BC stations, etc...

But... that would be messy and complicated.

Using a bridge with a tuned detector seems a much better approach. I do have an old MFJ Rx resistance bridge at hand, but I was looking for a little bit better accuracy. I must check e-bay, etc... for prices for a used bridge of the GR class you have.

My current problem could likly be solved by using one of my (so-called) VSWR meters, but I felt I might like to get a little more metrological capability for a few bucks.

I've never had a vertical antenna before and currently I'm laying out a radial field under a new vertical antenna. I just wanted to know when to stop laying down radials.

I figure that I just need to measure the input impedance of the antenna Zin at my frequencies of interest and record the (hopefully decreasing) impedance values as I lay down more radials. My assumption is that Zin = Zant + Rg. where Zant includes the reactance and radiation resistance of the radiator element at my frequency of interest and Rg is the ground resistance. Hopefully Rg should decrease as I add raials. I intend to quit adding radials when the impedance decrease becomes 'negligible' (In the sense of received S units [smile]).

Thanks again!

i presently have 3 analyzers... an mfj269 which i use for taking up
towers to check antennas when i have doubt about the coax or switch,
checking tuning real quick on anything, and doing simple cable loss
checks. then i have a minivna which i am still learning to use, but
which has proved very helpful in tuning stubs and checking filters.
it also does the tuning checks from the shack but requires a pc for
operation so wouldn't be very useful up a tower. my third one is a
home made tdr, just a decent scope and pulse generator set up to do
tdr on cables from the shack end. indispensable for finding damaged
cables, isolating bad connectors or relay boxes, etc. i wouldn't want
to be without any of them right now.

Yes, it is. I've done it, but a lot of care has to be taken that the filter doesn't have a significant effect on the impedance being measured. At best, it usually also restricts you to a relatively narrow bandwidth. It might be adequate for your particular purpose, however. But for the job you describe of evaluating a radial system, a simple homebrew resistance bridge is perfectly adequate. _Solid State Design for the Radio Amateur_ had some examples, and I assume its successor _Experimental Methods in RF Design_ does also.

If you're saying free isn't really free I can agree with you. I have
brewed my own beer (still do) and the realization was quickly
discovered that free isn't really free unless the hourly rate is zip,
zero, nada....

Paying consultants a kilobuck per day to support FOSS-based projects
starts looking pound-foolish very quickly. Training the in-house guy
to learn the ins and outs of a piece of FOSS doesn't work too well
either. If the guy is any good, he will soon be marketing his skills
as a $100+/hr consultant. In this aspect FOSS is just another form
vendor lock-in except the vendor is the consultant hawking his skills
and knowledge.

>Since MMANA-GAL and EZNEC
>have visual interfaces so similar, being able to use one is effectively
>being able to immediately use the other. The learning curve into your
>interface takes just a bit longer ...

Both provide immediate understanding but one immediacy takes longer
than the other? How different are skillsets for using a WIMP
interface?

>but, as you say, the availability
>of the source makes it highly desirable to at least one group.
>
The free in FOSS doesn't mean that anything is free of a learning
curve. In fact FOSS can actually present a learning wall. P2P support

tends to deal with solving specific problems rather than any abstract interpretation of what the problem is, why it exists (aka why the tool works as it does), and how best to resolve the specific issue.

The biggest problem with FOSS is too many freetards try to use the tools and fail to contribute what they have learned/experienced into any sort of public knowledge base.

I don't mean to denigrate FOSS at all. I'm just asking if FOSS is _the_ answer what was _the_ question? Too many know-nothings assume the tool is the answer and free means minimal effort/expense required. Only knowledgeable consumers ask how expensive is free.

Hi Pete, If you are evaluating a radial field for a vertical, then
the value you should be shooting for is 30-35 ohms, with no
reactance. As you know this is 1/2 the impedance of a 1/2 wave
dipole-70 ohms in free space. I have never done this, but an

impedance below 40 ohms with little reactance should provide you with an efficient vertical. Once you get around this value, I guess there is nothing to be gained by adding more radials. What your analyzer tells you, as others have mentioned, depends on the rf in the area.

Well, as you have seen, a concept such as "free" can mean many things to many different people, splitting hairs on that is only a waste of time some can engage in here ... However, I have downloaded the source, in C++, and have been making notes and stub testing various parts. One aspect of the source which really strikes me in the face, it is un-commented! Ya' just gotta luv that software engineer! ROFLOL

Regards,
JS

The actual value you get when the radial system loss is minimal depends on a number of factors, including the height and diameter of the vertical. I've also seen convergence to other resistance values when the ground was dry on the surface but apparently wet at some depth below. In that case, radial current can be significant at quite a distance from the antenna (as opposed to the exponential-looking decay you see in the current on radials buried in moist ground), making the system act more like a system of elevated radials. In those systems, radial length also plays a role in determining the feedpoint resistance value.

The bottom line is that I don't trust a single value or its comparison to 36 or 40 ohms as being a reliable indication of efficiency. You either need to look for convergence of the feedpoint resistance as Peter proposed, or even better yet, look for convergence of field strength values at a fixed location as you increase the number of radials.

Hi Pete, long time since I've seen a post from you on this NG!

Pete, I'd take Roy's route and use a GR impedance bridge. I've used the GR-1606A and the 1606B for the last 50 years. If you're not familiar with it it's been the standard impedance-measuring device for AM BC antennas for more than 50 years. It's accuracy cannot be beaten. These bridges were expensive when new, but they are available rather inexpensively now, and are stable as a rock. And as Roy said, they use either a millivolt meter or a tunable receiver as the detector. Using the receiver, interfering signals picked up with the antenna being measured are eliminated, thus not degrading the accuracy of the impedance measurement.

The GR-1606A measures from below 500 kHz up to 60 MHz. The GR-1602 measures well into the VHF range. If you should try one I know you'll like it.

Walt, W2DU

PS--If you'd like to see the results of measuring W2DU's antenna impedances, I refer you to Reflections, Chapter 15, Tables 15-4, 15-5, and Fig 15-1, which is a graph of the data in the Tables. If you don't have a copy of Reflections you can see this data on my web page at www.w2du.com. Just select 'Read Chapters from Reflections 2'.

Cross-posted to: sci.physics.electromag,rec.radio.amateur.antenna

Please, note that I experimentally confirmed -once again- that
NASA does not infinitely support direct linking to its
Technical Reports Server (NTRS) contents. Therefore, the link
given in article:

```
- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -
| Sent.....: Thursday, August 19, 2010 7:32 PM
| Newsgroups: sci.physics.electromag,rec.radio.amateur.antenna
| Subject...: Re: vemsa3d 1.1 - a floss visual em simulator for
| 3d antennas
| From.....: pez@grnet.gr
|
| ...
| J. H. Richmond, Radiation and Scattering by Thin-Wire
| Structures in the Complex Frequency Domain, (15), p.6
| http://tinyurl.com/24zwycy
| ...
- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -
```

is not a valid one anymore. One has to firstly connect to
NTRS:
http://ntrs.nasa.gov/search.jsp

and search for:
"Radiation and scattering by thin-wire structures in the
complex frequency domain"

or some adequate part of it, e.g. like the following one,
which it seems that currently holds:
"Radiation and scattering by thin-wire"

to get the Richmond's report item first and after two
more steps the full-text through "View PDF File".

Dear JS,

Thank you for pointed out this issue too!

As I already said, VEMSA3D is open source code, which is
distributed as free-libre; not free-gratis. Therefore, we
keep the right to publish full-comments about our source
code sometime in the future, as everybody else of course.
Please, see GNU GPL 3.0:
http://www.gnu.org/licenses/gpl.html

Free-gratis is the MS Windows application VEMSA3D, which
*everyone* can enjoy the production of it by simply following
the fully-commented instructions we already gave at the third
page, right column, of our paper:
http://arxiv.org/abs/1006.0031

Best regards,

pez, SV7BAX

Hi, there are quite many choices between tiny hand-held units like Autek
Research VA-1 vector analyzer and computer/laptop connected VNAs like
N2PK VNA which gives more accurate measurements. This last one is
basically a kit, but not too complicated to build at home and is quite
multi-use device.
Both have been useful and done their jobs well.

Kari B

[snip]

That's exactly what I thought.

Since; (a) I don't know my soil characteristics and (b) because of property limitations that dictate a non-uniform radial field, I felt that all I can do is to lay down radials in the property area I have avaliable until I see the change in Zin due to adding more radials become insignificant, then... I'm done!

I don't really care what the exact value of Zin = Rin + jXin ends up to be, since there is nothing I can do about it anyway. When I reach the point in laying down radials to where I can't reduce Zin much by adding more radials, I will then have the most efficient radial field with the lowest ground resistance Rg that I can get for my money and effort [smile].

Heh, heh... Money is only money, the effort, hmmm... well that's me crawling on my hands and knees for hours digging in the dirt (sand) in the blazing hot Florida sunshine, heat and humidity!

When I arrive at that point in burying radials, I believe that I can then tune out any reactive part of Zin with my 'tuner' and and end up feeding power into the remaining resistance Rin which then should be the sum of the vertical element radiation resistance Rr and whatever value I have ended up with for ground resistance Rg.

I just won't know what the value of Rr and Rg is, but I will know that I have achieved the most efficient radial field I could put down here at my place.

Is this right?

-- Pete k1po
-- Indialantic By-the-Sea, FL

PS: I took your advice and did some reading on simple impedance bridges, and I saw one that you had designed in one of my ARRL pubs. Cool!

Another idea I came upon that allow the use of those antenna analyzers in a situation where they can be somewhat immune to BC interference involved a two step process that went as follows...

(1) Hook up a transmitter through an antenna tuner to the antenna and ground systems under test and tune the tuner for zero reflected power with a 50 Ohm reflectometer (VSWR meter). Then (2) disconnect the tuner from the antenna, and without disturbing the tuner settings, hook a 50 Ohm load to the input side where the transmitter was connected, and then use the antenna analyzer to measure the impedance looking back into the output, or antenna terminals, of the tuner. This impedance should be the conjugate of Zin. Here the analyzer may not be as affected by potentially strong BC RF signals picked up by the lengthy antenna element.

Hi Pete, long time since I've seen a post from you on this NG!

Pete, I'd take Roy's route and use a GR impedance bridge. I've used the GR-1606A and the 1606B for the last 50 years. If you're not familiar with it it's been the standard impedance-measuring device for AM BC antennas for more than 50 years. It's accuracy cannot be beaten. These bridges were expensive when new, but they are available rather inexpensively now, and are stable as a rock. And as Roy said, they use either a millivolt meter or a tunable receiver as the detector. Using the receiver, interfering signals picked up with the antenna being measured are eliminated, thus not degrading the accuracy of the impedance measurement.

The GR-1606A measures from below 500 kHz up to 60 MHz. The GR-1602 measures well into the VHF range. If you should try one I know you'll like it.

Walt, W2DU

PS--If you'd like to see the results of measuring W2DU's antenna impedances, I refer you to Reflections, Chapter 15, Tables 15-4, 15-5, and Fig 15-1, which is a graph of the data in the Tables. If you don't have a copy of Reflections you can see this data on my web page at www.w2du.com. Just select 'Read Chapters from Reflections 2'.

Danny:

Hey thanks! I read your reference. Nice piece of work!

I guess I didn 't realize just how big those BC RF signals on the antenna element would actually be.
And for that matter, how little front end selectivity the analog inputs of those amateur antenna analyzers contain. None!

Hmmm... the amateur antenna analyzer sales literature I read don't mention this problem at all. The ads all 'brag' on the 'super features' of the devices. [smile]

I presume there must be more than a few dissappointed antenna analyzer purchasers who find this fact out the hard way.

Thanks again for the great reference.

Hi Pete, If you are evaluating a radial field for a vertical, then the value you should be shooting for is 30-35 ohms, with no reactance. As you know this is 1/2 the impedance of a 1/2 wave dipole-70 ohms in free space. I have never done this, but an impedance below 40 ohms with little reactance should provide you with an efficient vertical. Once you get around this value, I guess there is nothing to be gained by adding more radials. What your analyzer tells you, as others have mentioned, depends on the rf in the area.

Gary N4AST

My experience with the MFJ-269 agrees with Roy's -- fine for bench top measurements but nearly useless for antenna checks if you're close to high-powered broadcasters. (I'm even closer than he is!)

I have been thinking of an antenna impedance measurement setup using a HF bridge of some kind, driven by a high-level generator to swamp out the ambient junk. My 100 wattHF rig followed by a power attenuator (say, 10db?) would serve to drive the bridge, I would guess.

Anybody have some thoughts on this approach - pro or con? What kind of bridge would be good?

Larry Coyle, K1QW

Again, I would never look a gift horse in the mouth ... I don't find the lack of comments an surmountable problem. If you have a basic understanding of the concepts which a piece of software source deals with, it is relatively easy to locate them and comment/document them yourself. For example, when looking in software for routines and statements dealing with a circle, you would simple search for constructs dealing with area, circumference, diameter, etc. It is just a logical progression to look for those dealing with the implementation of the moment method. NEC source used in conjunction with these efforts makes it a tolerable exercise in reverse engineering the task ...

I see nothing wrong with expecting someone to do a bit of work to get something for "free", LOL.

Regards,
JS

You could just pass the coax though a suitable toroid. This toroid having a few turns of wire, rectification (diode) and some type of readout. This could easily be slid along the length of the coax and "relative measurements" taken. You could probably add some calculations and with the proper choice of components, actually get "real" readings. A simple turn of non-shorted coax around the inside circumference of the toroid, plus windings, would provide a measure of capacitance decoupling. I am sure, someone, somewhere has already done this and would have some meaningful data what is possible or what might be expected ... if nothing else, a "poor mans' indicator."

Hi Roy, I agree that field strength would be the best indicator of
efficiency as additional radials are laid down. However, for the
average Joe Ham trying to figure out how many radials is enough, and
all he has is an antenna anlyzer, what do you recommend?

Seems to me, with a 1/4 wave vertical of diameter large enough to
minimize I^2*R losses over average ground, if you add enough radials
to get the impedance to 35+/-j0 ohms as measured by the antenna
analyzer, you should be good to go. An additional check with the
analyzer could be the SWR bandwidth. If the swr was 1.7 across a
broad range then the 35 ohms is all ground losses. If the 1.7 swr

bandwidth is very narrow then you have a high Q antenna, and very efficient at the operating frequency. Does this make sense?

Gary N4AST

That's right! Since -as you already said- there are various
aspects of "free". Therefore, there is no field of application
of term 'reverse engineering' especially under the licenses
'Free Libre Source Code' and 'Public Domain Source Code',
since there is nothing there to disassembly it.

Moreover, under these licenses, ethics impose to give in return
at least as much as you get. This is especially holds in VEMSA3D
case, in which we get the Source Code included in J.H.Richmond's
report:

"Computer program for thin-wire structures in a homogeneous
conducting medium"

or just

"Computer program for thin-wire structures"

from NASA Technical Reports Server at:
http://ntrs.nasa.gov/search.jsp

in the way already described in message:
```

| : for 3d antennas
| Newsgroups: sci.physics.electromag,rec.radio.amateur.antenna
| From.....: <pez@grnet.gr>

Well, this source code has 1,044 lines of code, in 16 routines:

(1,044 = 100 + 61 + 158 + 36 + 9 + 98 + 120 + 104 + 40 + 64 +
+ 45 + 22 + 22 + 40 + 87 + 38)

and in return, we give for now:

* only 3 comment lines less than *

those exist among these 1,044 lines -as one can easily find
them in SGANT routine, at page 22, of the aforementioned
report.

Best regards,

pez, SV7BAX

It's a matter of how much you want to pay. If you want highly selective over the frequency range we generally use, you have to be prepared to pay and pay well.

Could be. As for Amateur use, there are lots of options. There's even a bare bones MFJ SWR tester that will be fine for 90 percent of what most of us want to do. Most amateurs just want a low SWR so their rigs don't fold back on power - for good or bad, that is the case.

Yes. Well, "reverse engineering", apparently, has many different meanings to many different people, as "free", also. However, all reverse engineering, done by engineers, does not involve a disassembler. Physical devices and concepts lend themselves well to reverse engineering, also.

I certainly have no interests in implementing any of this in a business/financial interest. And, since amateur radio itself demands the concept of "giving back"; It is a well known tradition. I see no conflicts with my directions, uses and interests.

NASA's contribution has already been paid for. NASA is the beneficiary of public funds ... I am sure the taxpayers say, "Thank you NASA;" I know I do.

I am sure you are already familiar with this, but never hurts to review when working with baluns/ununs:

"The maximum attenuation of a ferrite core is not where the inductance is maximum, but instead is where the magnitude of the impedance is maximum. This impedance peak may even be where the impedance has no inductive component nor capacitive component i.e. at resonance.

The frequencies that you are trying to attenuate determine the core that you should use."

One mans' experience and experiments here:
http://www.eham.net/articles/16319

As others have noted, it really is almost a case of you get what you pay for with antenna analyzers. Lesser models are prone to interference especially around high power installations and will give you only pieces of information you may need. One of my personal favorites is the TE-1000 'impedance analyzer' (http://www.lbagroup.com/technology/te1000-impedance-analyzer.php) made by TOMCO which measures pretty much everything you could hope for and has a high amount of protection from interference. I know several AM and even television broadcast guys that use this around towers without issues.

>
>
You've got two basic approaches to dealing with strong interference:
1) Make the signal you're measuring huge, so the interference is small..
any detector works
2) Use a tuned narrow band detector.

I would think you could use a simple resistive bridge with option #1,
although the tricky part is getting phase measurements. The current
crop of PC based VNAs and the like rely on having a handy quadradure
source. You could probably use a TAPR VNA, with a linear amplifier on
the Tx port and pads on the Rx port, after calibrating out the amp/pads.

A narrow band detector would be easier. This is sort of how the "noise
bridge" schemes work.. they use your HF receiver as the narrow band
detector. Again, almost any bridge would work for scalar (non-phase)
measurements.

Another approach is the old "three voltmeter meter" technique, which is
essentially a broadband detector and half a bridge, and lends itself to
high power.

The real challenge isn't in making the measurement, but in automating it
so that you can do a "sweep" conveniently. For spot measurements,
almost anything works well enough, but if you want to make 100
measurements it gets real tedious.

Thank you very much to correct me on this issue!

I did know the DocID existence but I did not realise,
until now, how it can be proved helpful. From the URL
```

you gave us for Richmond's report:

| http://hdl.handle.net/2060/19740013743

I found that 'hdl.handle.net' is a 'Handle Server', and
from NTRS item for this paper, I see that 19740013743 is
its DocID. In this way, and by experimentally replacing
this DOcID with '19890004330', I got the report titled
"Radiation and scattering ...". May now I think that
'2060' is some kind of ID in this Handle System for NTRS?
Where can I find more such IDs? Would you please advise me
more on this interesting subject?

Hi

Probably my comments are bit late... but OWA yagi's use direct feed to
driven element with a ferrite balun near the feedpoint.
OWA's give good impedance match in large bandwidth, this is based on
nearer driven element-first director spacing.
Otherwise gain, F/B etc. are very good.
I have constructed one 6m OWA yagi, with 20 ft boom as it was available,
using 7 elements in it, and finally with good match below
S 1.2 between 50...51 MHz.
Nothing critical in it, element dimensions were taken from NW3Z & WA3FET
article in OWA yagis, their 21MHz desing was re-scaled to 50MHz.
At least waterproofing is less critical in direct feed.

Actually, my MFJ catalog page for their antenna analyzers shows an
accessory, the mfj-731 "tunable analyzer filter." It's made for
operating an antenna analyzer in "presence of strong rf fields."

Personally, I have no experience with the filter -- my mfj-269 seems
to work okay, even with a 50-kw KTSA about a mile and a half away on
550 khz.

>> I see all kinds of crazy matching sections in posts about 6 meter
>> beams. How about direct connect.

Direct connect is used in a number of tribanders, but AFAIK it's not used in larger than 3L beams due to the low impedance. It can also distort the pattern, but with a 3L I doubt you'd notice. Just put 3 or 4 2.4", #32 mix toroids with 4 or 5 turns of feed line through them. It'll give the isolation and balance needed as long as the impedance at the feed point is correct.

>> I have an A4S that has major issues
>> in the traps and I cant find the problem (IE I opened them and cant

Problems in traps can be difficult to find. I had an ATB34 that appeared to have a trap problem but it turned out to be the feed line to driven element connection. They use 1/4-20 SS bolts through the insulators. The bolts simply press on the element inside the insulator. One was making a poor connection even though it felt tight. Taking it apart and cleaning the ends of the bolts and polishing the ends of the driven element where the bolts rested fixed it even though I could see nothing wrong at the time.

>> find anything) SOOO I have a new A4S coming.
>>
>> Has anyone taken an old 3 elem tribander and converted it to 6 meter

Spacing is generally far more than a little too wide.

>>
>> Would a 4 elem be better since its a long boom ?

Long boom? Tribanders come in a wide variety of lengths. If it's the typical 19 or 20', you are probably looking at around 5 elements.

Use one of the modeling programs, or get some to run it for you.

>>
>> I'm pretty sure I know the answers. Just want to confirm and see if
>> there is any reason not to direct connect rather than through a

There's really nothing particularly complicated about a hairpin or
gamma match. There are probably lots of designs that could be copied.

Water proofing the coax is very important, particularly when you get
to 50 MHz.

|
| Thank you very much to correct me on this issue!
|
| I did know the DocID existence but I did not realise,
| until now, how it can be proved helpful. From the URL
| you gave us for Richmond's report:
|
|| http://hdl.handle.net/2060/19740013743
|
| I found that 'hdl.handle.net' is a 'Handle Server', and
| from NTRS item for this paper, I see that 19740013743 is
| its DocID. In this way, and by experimentally replacing
| this DOcID with '19890004330', I got the report titled
| "Radiation and scattering ...". May now I think that
| '2060' is some kind of ID in this Handle System for NTRS?
| Where can I find more such IDs? Would you please advise me
| more on this interesting subject?

It seems that this is a somehow complicated matter...

Well, there is a basic FAQ here:
http://www.handle.net/faq.html
http://www.handle.net/overviews/handle-syntax.html

where I found that in the referenced by Jim Lux:
```

| http://hdl.handle.net/2060/19740013743

or in:

http://dx.doi.org/2060/19740013743

the couple of numbers '2060/19740013743' forms indeed
a unique 'handle' of which the two parts (numbers)
are known as:

<Handle Prefix>/<Handle Suffix>

or as

'unique naming authority'
/
'unique local name under this naming authority'.

Anyway, after I found
'The Internet Engineering Task Force (IETF)', of which:
'The goal of the IETF is to make the Internet work better':
http://www.ietf.org/

it made clearer that there is a registration procedure of
'naming authorities', as well as and this is definitely
a work which currently in progress, since on July 12, 2010,
the registered Name Assigning Authority Numbers (NAAN)
are only 54:
http://www.cdlib.org/services/uc3/naan_table.html

while among of them there is no NAAN for NASA or NTRS.

Anyway, this is really a very helpful reference system
for the Internet, but only *after* someone have search and
find the document which looked for, along with its unique
handle, of course.

Once again, thank you very much Mr. Lux for pointing out
this very interesting issue!

Just goes to show you, if you can think of it, most likely, someone else has already done it.

I would use a core with no air gap (but, if it was all I had, I'd use one such as the author of the article did.) If you have/like ferrite material, a FT114-43 (FT114-61, FT114-77, etc.) should work. If you like iron a T130-2, T130-6, etc. should work. I simply mention these because the ID would pass over a pl259 with a few turns of thin wire, larger ID toroids should be fine. I would think you can use whatever you have which will fit over the connectors you are using on your coax. Simply wrap the turns on the toroid, pull the connector off the tuner/rig, slip coax through, reconnect coax.

I just happened to have a T200-6 in a drawer here. So, I wrapped a few turns on, slipped it on the coax, ran the secondary through the 50ohm shut, diode/cap, and to a cheap VOM. With ~100w and the coax into a 50ohm dummy load, the reading I get is just reflecting the loss in the coax from the 95% braid I am using, most likely. With the coax from the ant, it appears it would be usable from 40 - 2m (bands limited to my antennas.) This should easily cover 160m to well below 2m. For SHF and EHF you may wish to choose a torid of differing material.

Thank you for finding and posting that article. It was a fun read!

JS

3599. Antenna rope replacement interval

Newsgroup: rec.radio.amateur.antenna
Date: 2010-08-27 15:54:39 UTC
From: Tim Shoppa <tshoppa@gmail.com>
Message-ID: <09d1ef76-c605-4fbd-af9c-2130c4ebb179@e14g2000yqe.googlegroups.com>
Source record: 7899

I've had a really nice 130-foot doublet fed by ladder line hanging between two trees for the past three years.

It's hung using 3/16" black UV-resistant polyester rope in the trees, and has a pulley and a 15-pound counterweight (plastic jug of sand) for tensioning at one end.

It's held up remarkably well over those three years, but I had noticed that the rope while still fundamentally flexible was kinda "hardening".

Where it went through the tree branches there was remarkably little wear over the three years. There was some black fluff where some chafing had occured but it still was holding up nicely.

But I went ahead and replaced all the rope anyway. With the tennis ball cannon I actually got the new rope hung a little bit higher than the old rope.

Just by touch, the new rope feels flexible and supple, and I contrast that with the old rope that isn't exactly "brittle" but does not feel nearly as flexible. The new rope felt kinda like a towel just having been washed and dried; the old rope felt kinda like a towel that had been used to mop the garage floor and then left lying there to dry. Maybe the feel was just grime and dirt that the rope had absorbed over the years?

I fixed a couple of broken ladder line insulators, and inspected the plastic end insulators too. The UV-rated polycarbonate that I had used for the insulators seemed to be holding up fine, although it was no longer crystal clear and had a good amount of grime and haze on it. Certainly didn't feel "brittle" yet.

I did replace the plastic jug of sand that's used as the counterweight. I had painted the jug brown and green to kinda blend in with the trees but even despite the paint layer I was a little worried about the plastic deteriorating there. On a previous antenna I had used a 1 gallon plastic milk container to hold the sand and that didn't even last a year before decaying. I'm using some darkroom container jugs now, with some extra reinforcement rope through the handle on the interior, and they seem to hold up OK.

Is three years a typical "good repair" replacement interval for ropes in trees? I think it probably could've stayed up another 10 to tell you the truth.

Re-hanging the antenna back up after replacing the rope felt so good.
It is beautiful to see it stretching from treetop to treetop one
hundred feet up.

The front end of many of these portable SW radios is typically "hot"
and has no problem hearing band noise with just the built-in antenna.
That doesn't mean that it's the world's most perfect antenna, it won't
hear nearly as good as something 100 feet up in the air, but it's fine
for the flamethrower SW stations.

But if you attach a longwire... you may find that you have intermod
issues with local AM/FM broadcasters. The front end in most of these
portable SW radios has very little preselection so they're susceptible
especially once you raise the local broadcasters to the level of
hundreds of millivolts. A tuner of some kind will help here.

Afternoon everyone,

I'm rebuilding my Bugcatcher antenna. It works well, but the XYL had a bit of an accident last year when we had a big snowstorm, the leaves weighted down the limbs, and the antenna, which was strapped down, still managed to introduce itself to a limb.

Anyhow, the original antenna was mounted using 1 inch thick plexiglass, with holes drilled to run the mast through, and tapped screw holes to mount to the back up plate, in turn mounted to the spare tire holder.

I'm trying to make something a little prettier now that I'm rebuilding it.

But the thing is, I'm curious about the material. Is there any particular material to avoid? I know Plexi works, but what about PVC? Delrin? Bondo? 8^) Miiling, water absorption, etc?

Polycarbonate, polycarbonate, polycarbonate.

It is way less brittle than plexiglass and far easier to machine and
work with.

It is a little more expensive than plexiglass.

Plexiglass is also know as acrylic. Polycarbonate is also known as
Lexan.

Polycarbonate is truly a wonderful material. I don't care what all
those people complaining about bisphenol-A say, polycarbonate is king.

Tim.

I have grown fond of nylon/teflon material, problem is, these materials
are difficult to find locally, and are expensive when found. In a
pinch, those plastic kitchen cutting boards are pressed into service
here. The are an opaque material, kind of "translucent white", softer
than plexiglass but hold up well under stress, will bend or warp rather
than break, seem to resist UV well enough, seem to exhibit good
insulation qualities up to VHF at least (highest freqs I have used them
at.) They can be cheaply had at used stores. They are usually 1/2
thick. Perhaps two sheets bonded or fastened together with brass/SS
hardware?

Locally findable is good. I may pick up some and try some machining
experiments. Nylon is certainly tough. Thanks, John.

My black UV resistant 'antenna rope' has been up 4 years and still feels very much like the 500' left on the spool. All is in our Gulf Coast sunlight except portions from the tree ends down from pulleys to hallard ties. Supports a G5RV 120' wire antenna. A second supports slopers for 40, 80 & 160. They stretch an inch or two between January (35') and August (96').

Fiberglass, fiberglass, and more fiberglass. It bends, it can easily
be repaired with a surfboard repair kit. It tolerates impacts better
than polycarbonate or plexiglass tubing. It's also UV resistant (when
coated with Krylon):
<http://www.mgs4u.com/fiberglass-tube-rod.htm>
$10 for 8ft of 1" plus shipping.

>Polycarbonate is truly a wonderful material. I don't care what all
>those people complaining about bisphenol-A say, polycarbonate is king.

There's some BPA in the epoxy resins used to bond the fiberglass matt
together. Don't drink out of your antenna, and you'll be fine.

Mike,
I use Delrin exclusively, great machining capabilities, and excellent RF
properties, very strong with excellent wear qualities, but make sure you use

the white product ONLY. If unsure, test it in the microwave on full power
for a minute along with a cup of water, and see whether it warms.

I have used it on all antennas from HF to UHF with no problems.
Use only 316 stainless steel hardware as well, less grief later on!

Polycarbonate, polycarbonate, polycarbonate.

It is way less brittle than plexiglass and far easier to machine and
work with.

It is a little more expensive than plexiglass.

Plexiglass is also know as acrylic. Polycarbonate is also known as
Lexan.

Polycarbonate is truly a wonderful material. I don't care what all
those people complaining about bisphenol-A say, polycarbonate is king.

Tim.

Agree, Lexan is the way to go.
If it is good enough for the canopy of an F-16 it is just about good enough
for anything.

Superconductors have been used as antennas where the gain has been
much much more than ham antennas. It does this by removing or
resisting the external magnetic field thus allowing the current flow
to exit the material and travel along its surface. Thus we are able to
reduce material
true resistance or losses and contribute solely to radiation.
By the same token, coils can be wound where it is totally resistive by
removing reactive forces. This also means the disappearance of skin
depth where the external magnetic field gains a foot hold. Thus, as
with a superconductor, we have removed the presence of resistive skin
depth resistance by allowing the current flow to exit the metallic
material and travel on its surface.
There are two resistances that must be dealt with in determining
efficiency where one is controlled by radiation that requires a equal
and opposite effect thus leaving only the metallic resistance to
concentrate upon
to increase efficiency. In both of the above cases we have been able
to divert current flow to the surface of the radiator to avoid the
intrinsic resistance of the radiating element, thus allowing all
alternating current flow to devote itself to creating radiation.

One of the most perplexing aurguements in the history of Physics is
the supposed existence of the Aether. Or in other words
Aether is has to be considered as a media.
In radio terms it can be stated that communication can be carried by a
surface wave only if it travels along the line of different media
which in physics is unshakable. Thus many physists argued that
air itself must be considered as a medium in that surface radio waves
certainly exist and thus the case against the existance of an Aether
has not yet been proven, as the question of the two mediums involved
have yet to be identified.
As I have stated earlier the expansion of the laws of static particles
show that particles from the Sun settle upon Earth's diamagnetic
surfaces. Thus providing the medium that purists have searched for
which now can replace the undeniable required presence of a medium
instead of the former "Aether". Classical physics of Newton, Einstein
and others had the answers all along with the Gaussian law of Statics!
Regards
Art
notion of an Aether.

It has been proven that "empty space" is indeed not empty and consists
of quantum particles that wink in and out of existence. Aether does
exist as a sort of quantum soup, just not in the limited form that was
earlier conceived in the past before quantum physics. The Casimir
effect is a manifestation of the quantum soup that exists in "empty
space". Some physicists think that's where the dark energy is hiding.

The article is about disagreements between scientists and not
agreement, therefore nothing is conclusive. What is conclusive that
making a static field dynamic shows the presence of particles in
Maxwell's equations on radiation.If you do not have the knowledge to
refute that fact then you have at your disposal the Physics Forum
where the adjudicators are generally professors in the field who can
provide you with the answers that you cannot find out for yourself.
Intuition alone does not get the job done so go to the experts to
verify your approach to physics. Classical physics clearly state that
particles from the Sun is incorporated in the art of radiation via the
extension to the laws of Static. If you want to over rule the
professors knowledge of physics then do it directly on their forum.

Where is the beef? Where is the patent? What exactly do you think the
patent is claiming?
Is the claim legitimate? Has the ham community
agreed on the removal of an external magnetic field for maximum
efficiency? You have consistently denied over the years and now
miraculesly you rush to defend it. Why are you so evil? As I stated
earlier your intuitions are leading you astray in the absence of
physics teachings or classes. Go to the Physics forum and ask for the
truth.

Whoa!You are talking apples and oranges. The two mediums discussed is
in actuality mass and particles where as it was considered as mass and
the Aether. I am certainly aware of the term quantum soup outside of
the Earths confines!
The two mediums of a radiator and particles is what provides for
ground wave and connected to
propagation. I don't think the scientists of the day were considering
propagation in outer space but I am willing to read any article that
supports your position
There are many positions and counter positions on the subject given by
most of the masters of the day.

Oh Art, this can be very taxing, but there is gravity, the method of the propagation of emf, and then there is dark matter, as Cecil threw in ... these are some of the last frontiers where discoveries will be finally be found.

I interpret Einsteins remarks on ether to be an admission that his theory of gravity would become undefined, if not for the "gravitational ether", not his exact words--his theory involving gravity depends up an ether. An ether composed of quantum particles would begin a solid discovery of how rf/light can behave both as particles and as waves. Gravity affects and can bend radio waves, obviously radio waves should have some effect on gravity, at sufficient energy levels. Dark mass appears to have an effect on gravity ... so in there is also a suggestion that these all have some profound form of relationship ... and it is here that "guesses", predictions, statements of bizarre magnitude and theories can abound ... I believe I can see your house, where you reside, down the street, just over there ... glad to see ya' still kickin', as long as you ain't breathing dirt, it is a good day.

<http://www.tangram.co.uk/TI-Polymer-PVC.html>
Electrical properties
The insulation properties of rigid PVC are satisfactory and
those of plasticised PVC are poor. The values, which are
only mediocre in any case, are impaired still further by the
plasticisers. As a result of the high dissipation factor,
PVC is not suitable for high frequency applications.

PVC has a dissipation factor of about 0.0350 compared to about 0.00610
for Polycarbonate.
<http://www.matweb.com>

Black PVC is also loaded with a small amount of carbon pigment, which
likes to get warm/hot/melt when RF is applied.

PVC is also subject to dielectric absorption. Build a capacitor out
of two plates with some PVC in between. Apply some DC, remove the
power source, and short the plates for 2 seconds. Then measure the
residual voltage across the plates. PVC and vinyl are awful. Teflon,
polystyrene, and polypropylene don't have this problem.

you should really talk with mr.b... he likes those old time scientists
and the stuff they wrote before all the real experiments disproved
aether and magnetic vortices and all that other stuff that you seem to
love. please write something new and funny about the magical
levitating diamagnetic neutrinos that explain how my ferromagnetic
antenna radiates.

I finally got around to read that patent you were referring to. It
involves the increase in radiation that can be achieved by

superconductors in temperatures way below that seen by humans.
for hams and industry using this knowledge by far the biggest expense
is the extreme cooling equipment that is required as evidenced by MRI
costs which is more than the most avid ham could afford. There is no
doubt that the repelling of external magnetic fields removes the
formation
of resistive skin depth of these ultra cool materials.
I advocate the use of the Meissner effect with antennas that does not
require the extensive cooling costs equipment required by
superconductors to remove the presence of the resistive skin effect
that superconductors have shown is very advantageous when designing
antennas. These are differences in both of these methods in removing
the unnecessary losses of magnetic field generation but the
commonality
between them is the increased efficiency in radiation. A side issue is
that the idea of smaller radiators is a reality as the idea of
radiators must be straight is totally false. The bottom line being
that every inch of current flow produces radiation
whether we like it or not and cannot be suppressed.
Tom, you should avoid trying to give the impression that you are
skilled in physics. You are not an engineer and you only work under a
engineers supervision because of your lack of knowledge.

Every time you put pen to paper it is painfully evident that you are
totally lacking in the subject of physics. A ferromagnetic antenna
will certainly radiate but it totally swamps the Meissner effect

common with diamagnetic materials. They certainly do not duplicate in actions with respect to radiation.
Most hams build their antennas with diamagnetic materials like copper and aluminum as they do not portray the hysteresis effect common with ferromagnetic materials. As for diamagnetic materials that demonstrate levitation you can buy these on E bay or at Edmonds scientific if you have any doubts about their authenticity.

but of course you can't radiate without generating a magnetic field
and any current produces a magnetic field so everything you are saying
is junk.

but how can it radiate if it doesn't have your magical diamagnetic neutrinos to levitate?? oh and to bring in one of mr. b's favorites, how do diamagnetic neutrinos accumulate on copper wire antennas if they are insulated... i'm sure he will love to hear your answer. he thinks electrons jump off the antenna and require a dc source to keep the antenna charged, you would love to chat with him!

Read, read again, then read again. The magnetic field referred to is
the EXTERNAL magnetic field.
A superconductor REJECTS any EXTERNAL magnetic field. With respect to
a "double helix" one can prevent the external magnetic field by
ensuring that the helix is resistive at all points along its length.
This results in a constant current along its length regardless of
frequency applied.
When amateurs in ham radio cling to the idea that radiators should be
straight they are advocating the generation of external magnetic
fields which only provides losses and less radiation. This is a spill
over from the old idea that waves produce
propagation instead of particles which is resisted
by the older generation who are adverse to change.
Tom you should not adopt the mantle which you have not earned as you
only are cheating yourself.
To others skilled in the art you are painfully transparent.

3639. Whip antennas with coils

Newsgroup: rec.radio.amateur.antenna
Date: 2010-08-29 02:23:44 UTC
From: Art Unwin <arthurunwin@gmail.com>
Message-ID: <df2f1e81-dc54-4951-a3b6-5316b61281f9@j8g2000yqd.googlegroups.com>
Source record: 7839

A long time ago there was a arguement both on this group and on E ham
with respect to the function of a coil with respect to replacing
missing degrees of a wavelength.
Both Tom W8ji and Roy W7EL did experiments which apparently justified
an account written up by Tom under the subject.
You should look it up and read it.
Tom states that the double helix is totally resistive and antenna
elements should be straight reffering to spacial distance.,
He then came to the astonishing conclusion that for maximum efficiency
radiators should be straight and for some reason dismissed the double
helix to give strength to his claim that radiators must be straight
which is fraudulent. A straight radiator generates a external magnetic
field which introduces losses whereas the double helix supplies all
applied current to the generation of radiation. None of the experts on
either group challenged challenged the statement allegedly supported
by both Tom and Roy
and it still remains in print to this day

I continued on reading Toms many dissertations on radiation and
antennas when I came across a lecture he gave at Dayton regarding
small antennas. Again he pushed his personal intuition with respect to
small antennas and spacial distance
and received no rebuttals from the audience or the ARRL . In addition
he always spouts his pet sentence on radiation is by the acceleration
of charge but never states what the charge carrier is
as he is still wedded to the idea of wave carriers which has no
justification what so ever. We desperately need the help from physics
majors to challenge the spread of old wives tales that are propagated
without technical justification and sucked in by the new generation of
which the hobby is now created or we lose the credibility obtained by
hams who foraged before us with respect to the state of the art.

I have an old alanice antenna rotor that was given to me. I have a question the rotor has 5 wires but the control box has 4 connections how do i wire up the rotor to the box? The rotor might be a old 100 or 200 u rotor. thanks for any help Robert

actually, probably none of my antennas are perfectly straight, all the yagi elements droop under their own weight. inverted V's follow a curved path and are of course not colinear, and in most cases not even in a plane. inverted L's aren't straight. my ferromagnetic radiators are probably the closest ones to straight, except for the one that was dropped on the way down one time and is a nice curved shape.

and you are wrong about superconductors rejecting external fields, they reject INTERNAL fields. you can have any field you want outside a superconductor. and double helixes are biological not electromagnetic, go take another basic calculus course if you think 'curl' is describing a vortex or helix.

You need to get a different control box. What you have is not
compatible. For example a T-20 rotor used a 4 wire connection and a
T-45 used a 5 wire.

I am completely ignorant of your "double helix" so I cannot comment on
that subject. I always thought a double helix was a strand of DNA.

On the subject of the number of degrees occupied by a loading coil,
both Tom and Roy made an incorrect assumption that rendered their
conclusions at best moot, and at worst false. Roy reported no
measurable phase shift in the current through a loading coil and
seemed to support the misconception that the phase shift is
proportional to the delay through the coil, which it is not.

Both Tom and Roy seemed to assume that the antenna current changes
phase by one electrical degree for each physical degree of antenna.
But EZNEC easily proves that to be an incorrect assumption for the
current in a standing-wave antenna which includes dipoles, monopoles,
and loaded mobile antennas. The following applies to 1/2WL dipoles and
1/4WL monopoles including loaded mobile antennas.

THE PHASE OF THE NET CURRENT IN A STANDING-WAVE ANTENNA CHANGES VERY
LITTLE BETWEEN THE FEEDPOINT AND THE TIP END OF THE ANTENNA.

*The phase of that current cannot be used to calculate the delay
through a wire or through a loading coil.* The phase of the net
current in a thin-wire 1/4WL monopole changes by ~3 degrees over a 90
degree physical length. The same is true for a loaded mobile antenna.
Anyone assuming that signal delay is proportional to current phase
shift in a standing wave antenna is off by a magnitude or more. Tom's
reported 3 ns delay through his coil is about 12% of the actual value
of the delay at 4MHz.

The following inductance calculator can be used to estimate the delay
through a loading coil. The parameter to use is the "Beta = rad/m,
Axial propagation factor of n=0 sheath helix waveguide mode at design
frequency[1,8]'

http://hamwaves.com/antennas/inductance.html

The rad/m of the axial propagation factor can be used to calculate the
number of degrees occupied by the specified loading coil and the
velocity factor of the loading coil. The 100T, 10" coil that Tom used
for his "measurements" has a delay of ~30 degrees at 4 MHz, virtually

unrelated to the phase-shift in the standing-wave current that he reported. Delay is NOT proportional to current phase-shift on a standing-wave antenna and certainly not for the loading coils on a standing wave antenna. However, delay is proportional to current phase-shift on a traveling-wave antenna.

Of course, but apples and oranges are both particles. The old masters were correct about the aether consisting of particles - they were just wrong about the nature of the particles.

If someone hits you in the head with a frozen apple or a frozen orange in the dark on a winter night, it is difficult to tell the difference. Quantum physics has turned on the light.

Here's a quote from "Fields and Waves ...", by Ramo and Whinnery:

"A perfect conductor is usually understood to be a material in which
there is no electric field at any frequency. Maxwell's equations
ensure that there is then also no time-varying magnetic field in the
perfect conductor."

I have two NEC 536300 relays for sale. The specs are:

50 ohms input and output
150 Watts to 470 MHz
VSWR 1.25:1
Crosstalk 40 dB
12 VDC coil
Shown in August 1965 VHFer if you still have it. I don't.

They can be viewed at:

http://home.comcast.net/~hsknoll/site/?/photos/&PHPSESSID=29ec62ea0bf1fe4d25e318b011cf0bbf

or

http://tinyurl.com/yktwxpz click on photo to enlarge it.

I'm asking $10 each plus shipping.
==========
I have a Heath HM-2102 VHF SWR meter 50-160 MHz
0-25 and 0-250 watts. Very good condition.

I'm *asking* $40 plus shipping.

It can be viewed at:

The purpose and function of a loading coil used with an electrically short antenna is to offset the capacitive reactance of the short radiating section. Otherwise it will not accept much power from a transmitter or deliver much power to a receiver, due to a very high mismatch to common types of transmission line connected to its terminals.

Check this using a simple NEC model. The model will have ~ the same radiation resistance, radiation pattern, and gain in dBi whether or not a loading coil at the feedpoint makes the antenna system resonant, other things equal.

J. Kraus states in the link below that the radiation resistance of a loaded vertical (for instance) is nearly the same as that of an unloaded vertical of the same height.

That a loading coil contributes "missing degrees" to resonate a short antenna is rather a specious concept.

On the helix coil, of any helical wound loading coil, or even a linear loaded monopole/dipole, you can wind another helix, in between the turns of the first helix, both ends are open and not connected. This tends to expand the antennas' bandwidth, "normalize" ant impedance, etc.

That is the only thing I can figure he is referring to ...

Having locked myself away for months, wife will claim years, and searching for the "best" shortened stealth antenna(s), I have been forced to employ coils. In any loaded antenna (hide the JD!) the coil is best at the bottom with a .62 L/D ratio. I currently use DLM's from Robert Vincents' patent, it allows me to break the laws ... others research and mileage may vary.

The loading coil adds +J to compensate the -J from a short antenna ... however, old hams taught me that the coil adds electrical degrees, God bless them ...

You can make it work but it will be Full Manual -- no indicator. The
motor has two coils; the high side of each coil has its own terminal;
the low sides are tied together to another terminal. These three
terminals are powered from a corresponding trio of terminals on the
box, two hots and a common.

The trick to CW or CCW rotation is that one of the hot terminals is
driven directly and the other is driven through a capacitor. The
control box switches the capacitor into one lead or the other,
according to which way you twisted the knob or pressed the lever.

A clever fellow with a multimeter could identify which terminals
belong to which function (on each unit) and connect accordingly.

Tom and Roy both measured *net* current - they did not use a
directional coupler. If they had used a directional coupler to measure
the current, they would have measured ~30 degrees shift in both the
forward current and reflected current through an 80m loading coil.

Let's talk about the net current in a 1/4WL lossless shorted stub.
Have you never looked at that equation? What is the phase-shift in the
net current from end to end in that stub? Exactly how do you
rationalize zero degrees phase-shift in the current in a stub known to
be 90 degrees in length?

Uh Richard, how does it accomplish that feat without a phase shift?
Aren't -jX and +jX, 180 degrees out of phase? Exactly how is a -jX
offset without a 180 degree phase shift?

In an electrical 1/4WL standing-wave antenna, like an 80m mobile
antenna, the phase shift between the forward wave at the feedpoint and
the incident reflected wave at the feedpoint is obviously 180 degrees.
Exactly how is that accomplished without a phase shift in the loading
coil?

There is a logical intuitive way to arrive at the phase shift through
a loading coil. Would you like to hear about it?

If the loading coil used to resonate an electrically short vertical really contributed '"electrical degrees" arising from some attribute(s) of the coil that made the short antenna system the full electrical equivalent of an unloaded, 1/4-wave vertical, then please explain why the loaded version does not have the radiation resistance, and typically the radiation efficiency of the unloaded version.

The radiation resistance and radiation efficiency of a short antenna,
like any other antenna, depends upon the *physical* length of the
antenna. Nothing can be done about that fact of physics where bigger
is generally better. Short resonant antennas have a lower radiation
resistance and therefore lower efficiency. Please do not confuse
radiation resistance and antenna efficiency with feedpoint impedance
where the reflected wave must arrive 180/360 deg in phase with the
forward wave for the feedpoint impedance to be resistive and resonant.
There is simply no other possibility.

The *feedpoint impedance* of a standing-wave antenna depends upon the
electrical length of the antenna. If it is resistive, the reflected
wave has undergone at least a 180 degree phase shift referenced to the
forward wave. Otherwise, the feedpoint impedance would not be purely
resistive. Make no mistake, a typical loaded mobile antenna is 90
degrees long and part of that 90 degrees is furnished by the loading
coil. Note that I said "part", not *all* of the "missing" degrees.
W8JI is correct about approximately half of the phase shift between
the coil and the stinger. He is 100% wrong about the other half of the
phase shift which occurs within the coil.

Here's a question for you: If the feedpoint impedance of a loaded
standing-wave (mobile) antenna is purely resistive, how could the
reflected wave arriving at the feedpoint have undergone anything
except a 180 degree phase shift?

Why is the feedpoint impedance of a resonant short loaded antenna
usually less than that of a 1/4WL antenna? Because the radiation
resistance is lower and the I^2*R losses are lower. But all resonant
shortened monopoles are 90 degrees in electrical length. Anyone
arguing against that fact of physics is just ignorant of how standing-
wave antennas work. That includes some otherwise knowledgeable
"gurus", incapable of admitting a mortal mistake, who post to this
newsgroup.

> . . .

Difficulty in getting power to an antenna is due to the mismatch between the transmitter and the impedance it sees, rather than between the transmission line and antenna.

As a simple example, consider a 75 ohm dipole connected to a transmitter through a half wavelength of 600 ohm transmission line. The transmitter sees 75 ohms. Most transmitters will deliver full power to a load of that impedance and, except for line loss, all that power is delivered to the antenna in spite of a 12:1 mismatch between the transmitter and transmission line (assuming a 50 ohm output transmitter) and 8:1 mismatch between the transmission line and antenna. If you change the transmission line impedance to 75 ohms, the transmitter can't tell the difference -- it still sees 75 ohms and delivers the same amount of power, even though the line and antenna are now perfectly matched.

> . . .

For many years I've used a slingshot to put up antennas on Field Day. Even after just a day or two, they can sometimes be hard to get down, the twine having dug its way into the tree and gotten gummed up with sap. After those experiences, I've never been willing to put an antenna up permanently or semi-permanently by just getting a rope over a branch -- I've climbed and put a pulley part way up which I've had to replace every few years as the tree grows out over it.

Of course, larger diameter rope wouldn't cut into the tree as badly as the heavy twine I use for FD. But I'm sure it would still cut in and get stuck after even a fairly short period of chafing under tension, and the tree would grow over and around the rope before long. The result would be a rope permanently stuck in the tree.

So I'm curious how this ends up working for you. My trees are nearly all confers -- Douglas Fir, hemlock, sequoia. Are yours hardwood? Are other folks able to get away with this?

standing-wave (mobile) antenna is purely resistive, how could the
reflected wave arriving at the feedpoint have undergone anything
except a 180 degree phase shift?

There are the two possibilities: See:
http://paws.kettering.edu/~drussell/Demos/reflect/reflect.html

1.Reflection from a HARD boundary "at a fixed (hard) boundary, the
displacement remains zero and the reflected wave changes its polarity
(undergoes a 180o phase change) "

2. Reflection from a SOFT boundary " at a free (soft) boundary, the
restoring force is zero and the reflected wave has the same polarity (no
phase change) as the incident wave "

So if the feedpoint is in distance 1/4 WL from the end you have 0 or 180
degree phase shift.

Which case is in antennas?

However an assumption might be taken from some posts here that a short vertical radiator loaded to resonance is the full electrical equivalent of an unloaded, resonant vertical of about 1/4-wavelength, while it is not. That is my point.

Rather than using an example of a balanced antenna having reasonably high radiation resistance and zero or low reactance at its input terminals, let us consider a base-fed 10 foot whip at 3.8 MHz -- which is more along the lines of this thread.

Without using a loading coil, the input Z of that whip is about 0.6 -j 1250 ohms. The SWR that this antenna input Z presents to unmatched 50 to 600 ohm transmission line ranges from 52,167:1 to 5,340:1.

Not much power will be transferred through such a match, which is the reason for the statements in my quote which you referred to.

The short vertical radiator loaded to resonance *IS* the full *electrical* length of an unloaded, resonant vertical of about 1/4WL, which is related to the feedpoint impedance. It is NOT the full *physical* length which is related to radiation resistance and efficiency.

The feedpoint impedance of any electrically long 90 degree standing-wave antenna, including resonant loaded mobile antennas, is:

Zfp = (Vfor-Vref)/(Ifor+Iref) on the antenna, not on the feedline.

The reflected voltage has undergone a 180 degree phase shift. The reflected current has undergone a 360 degree phase shift. Part of the phase shift occurs in the loading coil. A typical resonant mobile antenna is *electrically* 90 degrees long. If it was less than 90 degrees long *electrically* it would exhibit capacitive reactance at the feedpoint.

Let's discuss a base-loaded configuration which is less complicated than a center-loaded configuration. (1) The delay through the loading coil is part of that 90 degrees. (2) The delay through the stinger is part of that 90 degrees. (3) The phase shift at the coil to stinger junction is part of the 90 degrees. Tom, W8JI, assumes a lumped inductor for calculating the phase shift at the coil to stinger junction but a 75m bugcatcher loading coil is NOT a lumped inductor - it is a distributed network existing in the real world with an associated real-world delay through the coil.

The other rail of the argument assumes all of the "missing degrees" come from the coil and none from the coil to stinger junction. Both sides are wrong. All three phase shift components listed above exist in a base-loaded mobile antenna.

(There are four phase shift components in a center-loaded mobile antenna. Degrees of electrical length are actually lost at the low Z0 base section to high Z0 loading coil junction. That's why the inductance (coil delay) has to increase for center-loaded configurations.)

Interestingly enough, a base-loaded mobile antenna functions like the dual-Z0 stubs covered on my web page and can be analyzed in the same manner:

http://www.w5dxp.com/shrtstub.htm

Here is a simplified approximate representation of what a base-loaded mobile antenna looks like electrically:

FP------Z01=5000 ohms------+------Z02=500 ohms------

The Z01 portion is the base loading coil and the Z02 portion is the stinger. The Z0 of the loading coil can be obtained from the inductance calculator at:

http://hamwaves.com/antennas/inductance.html

A 10 foot whip at 3.8 MHz is about 0.0386 wavelength or about 14
degrees. That's about -j4.0 on a Smith Chart. Can we say that -j1250/
Z0 = -j4.0? such that the Z0 characteristic impedance of the whip at
that input Z is ~312.5 ohms?

Roy -
Let me tell you, I could never be good enough with a slingshot to get a line over a 120 foot tree! But the tennis ball cannon has served quite nicely for sending a line over any tree I could find. We could probably agree to disagree on this - you're good with the slingshot, and I'm an ace with the cannon.

I find that even in non-conifer trees that it's likely for a 1/4" or 3/16" rope to get stuck after a year or more. If there's a single crotch with a tight angle in it (e.g. 90 degrees) as opposed to a number of turns of smaller angles it seems more likely to get stuck. I don't see how twine could hold up for nearly that long. My installations are Dacron/polyester rope with pulleys and a counterweight; the counterweight is IMHO absolutely essential to having the antenna survive a thunderstorm.

There are also fast-growing pine trees in my neighborhood but they are "new" and not the giant old-growth trees. In the February snowstorms (4 feet of snow! Snowpocalypse!) a *lot* of the medium height pines came down under the weight of the 4 foot snowfall. Non-evergreen trees also came down but not nearly at the rate that the conifers did.

Hi,

I've noticed most homebuilt amateur antennas use tubing and usually copper,
whereas commercial antennas typically use round bar, either steel or Aluminum.

I understand the advantages of the materials in terms of electrical conductivity and weather resistance,
however I dont understand the pro's and cons of using tube vs round bar? Can you point me to
a book that may discuss this?

Have studies been done re the effect of a layer of oxidation on the performance of the antenna?

Finally, there is plenty of material about designing antennae for a band, but every little about designing it at a particular impedence,
can you point me to a discussion on this too?

Thanks

Steven

Hi Steven,

No book necessary. Walk into a store that sells any of this and you
will tell several things immediately:
1. what is available;
2. what is affordable;
3. which weighs more for no increase in performance.

>Have studies been done re the effect of a layer of oxidation on the
>performance of the antenna?

Oxidation is another form of insulation. Lots of antennas are
insulated. They have been studied galore. If the oxidation becomes
as thick as a vinyl jacket on your coax, then the antenna is going to
resonate at a lower frequency.

>Finally, there is plenty of material about designing antennae for a
>band, but every little about designing it at a particular impedence,
>can you point me to a discussion on this too?

Those references are too numerous to recite in one place - that is
what google is for. To the nature of your question, there is no
reliable "formula" for all styles of antenna that can provide a
satisfactory answer. Even simple antennas have complex relationships.

Electrically there is not much differance in using tubing or rods. It is
mainly about the cost, weight and strength.

Copper is used by many at home because you can get it at the local stores
where aluminum is often hard to come by in lots of towns. Also you can
solder to copper where not many can solder or weld aluminum.

The impedance is not usually that much concern, Just design for gain and
f/b ratio and then match whatever impedance you have to the transmission
line you are going to use.

Copper has the advantages that copper pipe and fittings are available at any hardware store or home improvement store. Aluminum isn't exactly rare but it's not so easy to find in your hometown on a Sunday afternoon at a retail store.

Copper is also easily joined with solder by just about anyone using very simple tools. Aluminum can be welded but this requires more skill and a welding machine.

Aluminum is a superior antenna material in terms of strength per dollar or strength per weight, but not quite as readily available.

Very few aluminum antenna designs use solid bar, with the exception of VHF/UHF or tips where the elements are so skinny that there's no point to making them hollow. The vast majority of HF aluminum antennas are not solid bar but nested sections of aluminum tubing. The ham radio magazines have lots of ads in the back from places that sell nesting aluminum tubing sections.

I don't think there is any substantial electrical difference in copper vs aluminum oxidation. Play with EZNEC varying the conductivities and you'll find that the conductivity changes are in the noise.

One important thread in these antenna designs, is not that they are numerically superior in performance to some other technique. It's that

they're buildable by average hams using readily available materials.

Tim.

In the above "equivalent" is used in an interesting way. If equivalent
is used as a term of efficiency, you are absolutely correct. If you are
saying my transmitter still knows the difference between a "straight"
1/4 wave and an "equivalent loaded" antenna, the use becomes false ...
i.e., when I dip the loaded antenna with my GDO, and the antenna is
properly constructed, it tells me I have the "true" equivalent of a 1/4
wave.

Mike as I understand it Aether theory started with the motion that if
two mediums meet then a electron
can pass thru both mediums OR travel between two mediums. I suppose
you can look at the Universe that way starting

and then going thru a progression of different mediums until you come
to the end or the last medium. If you put together two pieces of glass
in sandwich fashion a electron, say light, may travel thru both pieces
of glass AND/OR along the path
between the two pieces of glass.
Thus the exercise starts with Earth itself and then one determines the
next medium and so on until one reaches the outer Galaxy. Now in a
particular case scientists came across a dilemma where a path of light
existed parallel to a medium but they could not determine exactly what
the next medium was. Thus was brought forward the term Aether
as a stop gap term until the medium could be truely determined.

Visible energy/matter can occupy the same space as dark energy/matter,
much like solid salt and water can occupy the same space. Just as the
salt contributes to the mass contained in the water, visible mass
contributes to the mass occupied by dark matter.

Power will indeed be transferred through such a match. Using your antenna as an example, suppose that a transmitter with output Z of 50 ohms is connected to a tuner that transforms its output impedance to 0.6 + j1250 ohms. Connect the output of the tuner to a half wavelength 600 ohm transmission line to the antenna. The transmitter will see 50 + j0 ohms, the antenna will see an impedance of 0.6 + j1250 ohms, and full power will be transferred. Power transfer has nothing to do with the SWR on the line or the match between the line and antenna.

In practice, the line loss will increase some due to the very high SWR, but the loss increase won't be much if the matched line loss is low.

I chose a half wavelength for simplicity, but it's not necessary. Other lengths of line will transform the antenna impedance to different values. All that's necessary is to readjust the tuner accordingly to match the different impedance.

Amateurs have successfully been using this method to feed nonresonant and multi-band antennas for decades.

I wasn't intending to argue about the best method to put a line over a tree -- I backpack my portable station as well as camping equipment on Field Day, which is why my choice of a slingshot and twine. My best height with it is about 100 feet, but I usually choose my FD sites for sloping terrain to the east so I don't need much height. My question is only about the problem of a line getting stuck after a short while. I've assumed that conifers are more of a problem because of the sticky pitch and relatively soft wood. What are the experiences others have had with moderately sized line?

Try this.

When you replace the rope, put up an extra length of rope with nothing attached to it. I have a rope over the limbs to two trees; trees are about 160 feet apart, which accommodates a 135-foot doublet fed with open-wire line.

I installed, over each tree limb, next to the ropes that hold the antenna, another rope that is simply a long loop -- goes from the ground to the limb, over the limb, and back down to the ground. There's no strain on this rope -- actually, two ropes, one over each limb where the antenna is supported. That way, if the rope holding the antenna breaks, I already have a spare rope installed -- just use it to haul up a new antenna support rope -- no need to haul out the slingshot.

3688. Re: Superconductors and Ham antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2010-08-30 21:22:11 UTC

Source record: 7788

The lack of comprehension of fundamental physics on this newsgroup is astounding, so it's no surprise that a less-known fact has been missed:

A superconductor has zero resistance only at DC. The resistance at RF depends, among other things, the frequency and the material's temperature. Because the resistivity of copper drops dramatically at cryogenic temperatures, it can be difficult to make a superconductor with resistance as low as copper at the same temperature.

Very small superconducting antennas have been demonstrated, but they still have a very large near field which sustains loss by coupling to nearby objects, and a large reactance which necessitates potentially lossy matching networks.

Since you are so familiar with the concept why not start from Earth
with a progression until you get to Aether. I don't think you will get
to your favorite "dark matter" For that matter explain what a "medium"
is in physics terms.

Roy,

The mention of reactance means we are talking in the frequency domain,
and a steady state solution is being discussed.

Roy Lewallen <w7el@eznec.com> wrote in
news:kpudnRnpGI6kj-HRnZ2dnUVZ_vqdnZ2d@giganews.com:

> 0.6 + j1250 ohms. Connect the output of the tuner to a half wavelength

Does the use of "output impedance" here mean that he transmitter can be
validly represented by a Thevenin equivalent circuit, and that "output
impedance" is the Thevenin equivalent source impedance.

Without getting into that arguable postion and reinforcing the notion
that a transmitter rated for a nominal 50 ohm load has a source impedance
of 50+j0, you could say:

... Using your antenna as an example, suppose that a transmitter designed
to operate into a load Z of 50+j0 ohms is connected to a tuner that
transforms the antenna (0.5-j1250) to its preferred load impedance (50
+j0). Connect ...

> 600 ohm transmission line to the antenna. The transmitter will see 50

And:

All that's necessary is to readjust the tuner accordingly to deliver the
transmitter its rated load impedance.

>
> Amateurs have successfully been using this method to feed nonresonant
> and multi-band antennas for decades.
>
> Roy Lewallen, W7EL
>

As you will have noted, some band the term 'match' around with abandon, and it means different things in different contexts, and to different readers.

Take a transmitter designed for a 50+j0 load, connected by an electrical half wave of 70 ohm coax to a 50 ohm load. Is it 'matched'? Well, from the information, it is correctly loaded, it is designed for a 50+j0 load, and it has a 50+j0 (approximately) load. We don't actually know the source impedance, and even if we did, it this case, whether the transmitter is 'matched' to the line, and whether the line is 'matched' to the load is unimportant.

'Output impedance' is another term that is used differently, some use it to mean the equivalent source impedance, some to mean the required load, and some insist the foregoing are naturally the same, or will be if the transmitter is 'matched' for maximum power output.

Owen

I did. You stated:

> Without using a loading coil, the input Z of that whip is about 0.6 -j
> 1250 ohms. The SWR that this antenna input Z presents to unmatched 50
> to 600 ohm transmission line ranges from 52,167:1 to 5,340:1.

In my example, the antenna is not matched to the transmission line. Nor, for that matter, is the transmitter matched to the transmission line. My point is that power transfer doesn't depend on either of these points being matched.

Art, you don't seem to understand that there is a quantum base medium
to which some other medium may or may not be added. The base medium
exists throughout all of universal space and is the only medium that
exists in otherwise empty space. Any other added medium, e.g. air or
water, is just mixed with that base medium. Please stop thinking with
a concrete brain.

Dear Group:

I add a vote for avoiding the arguable position about the "output Z" of
a transmitter (note, transmitter) and instead using words similar to those
used by Mr. Owen Duffy: a transmitter designed to operate into a load Z of
50+j0 ohms

Conclusions reached with a minimum of needed assumptions are preferred.
Roy's observations do not require a particular output Z and are true.

A signal generator with an emitter-follower output stage having a 50 ohm
resistor in series with the output port can have an output Z of very close
to 50 ohms over a broad frequency range.

this one sounds like a religious argument to me... to phase shift or
not to phase shift, that is the degrees of shortening... weather tis
nobler to count the degrees or accept the time delay traveling waves,
one way or another there is still high voltage at the top and high
current at the bottom, and never the twain shall meet.

instead of electrons jumping off the antenna art charges it with
magical levitating diamagnetic neutrinos that flow out from the sun
during sunspots to fly off the antenna. that would be the same
mechanism that those other scientist dream of for affecting
radioactive decay.

Zero resistance is not strictly a function of direct current. It is simply the most often reported experimental characteristic in the popular press. Impracticality of the additional RF characteristic (which I presume in this forum to be confined to UHF and below) is unwarranted in materials research at this point, but EHF/IR and above results are frequently reported in association with other research - plasmonics and phonon/electron interaction.

The resistivity of copper falls with temperature, true, but we encounter diminishing returns as we approach absolute zero: the drop fails to follow through to the expected final zero resistance. This was an experimental dissappointment decades ago. Silver and gold are rarely chosen for their electrical properties in the nano-dimension - chilled or otherwise (although gold is suitable, gold is far more useful in association with thiols). In fact, what are typically poor conductors exhibit less low temperature resistance than copper (cold or warm). I won't go into that list, it is enough to consider that such "wires" would be confined to thin film depositions on a flexible tape substrate - pretty exotic.

Going further, it isn't even necessary to drive temperatures to the basement for improved conduction. Carbon nanotubes are exemplars of high conductivity (several orders of magnitude better than what we consider good metals) at room temperature where a carbon macrotube would be called a resistor. Conductivity and superconductivity research has long ago left the realm of temperature and has entered the realm of crystal alignment.

However, even this academic. Carbon Nanotube construction at a scale to compete with standard copper wire is off by a scale of a million to billions (of dollars, much less practicability).

> Johnny come lately, Aether theory.

Are many of Aether theories:
http://en.wikipedia.org/wiki/Timeline_of_luminiferous_aether

Some of them were erroneous.
But the question what is the medium for radio waves remain.

There are the two issues. Is it movable or not and what is made of.

The first was judged by Michelson:

"1925 - the Michelson-Gale-Pearson experiment produces a positive result while attempting to detect the effect of Earth's rotation on the velocity of light. The significance of the experiment remains debated to this day, but this planetary Sagnac effect is measured by ring laser gyros and taken into account by the GPS system."

So we know that the aether rotate with the Sun but not rotate with The Earth.

The last proposition for the second was made by Dirac. In space is en electron see. So the medium for radio waves are free electrons. In the space are also ions, atoms and dust. It has name Interstellar Medium (ISM).

In the "physics terms" the base medium is Dirac electrons see.
The "added medium" are ions, atoms and dust. All are produced by Stars.

The same mixture is in metals. In metals the free electrons are medium for
the electric waves and ions and atoms for the acoustic waves.

Maxwell-Heaviside ether was like the dielectric.
The todays ether is like rare plasma. Plasma is a conductor.

> Frankly I just do not understand your response.

Outside of the space-volume of the universe, there is no structure.
Inside the space-volume of the universe, there is an invisible quantum
structure everywhere. You live and function within that structure
without being aware of it. That quantum structure may or may not
contain visible matter/energy which can modify the electromagnetic
characteristics of the medium, but does NOT replace the quantum
structure as you appear to think. The quantum structure is the
container of everything that exists. Nothing exists outside of the
container (unless there are more unconnected containers somewhere
else).

Air, water, or earth does not displace the quantum structure but
gravity can warp it, e.g. black holes. Everything that exists in our
universe is contained within the invisible quantum structure which
appears to consist of dark matter interacting with dark energy. It is
believed that the pressure of the dark energy is overwhelming gravity
and is causing the expansion of the universe.

I'll drink to that. Consider a transmitter connected to an antenna
tuner by a piece of 50 ohm coax where the SWR is an ideal 1:1 on that
short piece of coax. There are no reflected waves on the coax.
Therefore, no reflected energy reaches the source. Energy transfer is
a one-way process on that flat piece of coax. Except for efficiency,
the source impedance doesn't matter. Whether the source impedance is
10 ohms, or 50 ohms, or 200 ohms, dissipative or non-dissipative,
reactive or resistive - just doesn't matter. All that matters is the
voltage delivered to the 50 ohm Z0-match at the tuner input.

Cecil as I stated before a electron can travel thru
two mediums OR along the path between the two mediums. The presence of
surface wave of propagation points to another medium whether it be
between Earth and the atmosphere OR the atmosphere is a medium itself.
It is because of this
electron travel along the surface of Earth that scientists come to the
conclusion that the atmosphere is a medium which they name.
This is not accepted by mainstream but to be fair mainstream has not
named or explained the medium that allowed for over the surface
electron travel.
From my point of view the "missing" medium is a carpet of free
electrons that are bound in a skin as seen on surface tension on water
and it is this skin
or carpet upon Earth is the medium that explains the surface travel of
electrons, a missing medium that satisfies both sides of the puzzle.

By golly, I believe you are getting it ... except for you focus on "a surface." We have a medium to test all this with, which is quite suitable. Water; No surface is needed to produce sound within a body of water, itself, water serving as the example of "ether." A very strong, varying, magnetic field, in the audio range, can work upon the slightly magnetic atoms producing the sound. In passing, "pumps", which may someday propel vessels, can also use this effect to "pump" water though a coil and propel the vessel. Ether should be able to be manipulated in a like manner ... now, unless you show up upon my doorstep with a workable model of an "ether antenna", this all has, and will remain, of little use. However, I think you are just the man to do it, Art. <wink>

Just when I thought you were getting it too ... you need no dust, no matter which you can touch, to have emf produced and transverse-ing the universe(s.) See, you are still focused on that "surface."

John
Cecils interpretation of a double helix was what is termed as the
secret of life with is the combination

of two vectors direct an circular or spin which generated the double helix. This can also be explained as the secret of everything in the scientific world whether it be the two vectors created by the BIG BANG or the two vectors of gravity and rotation and on to the two vectors as an electron travels between two mediums. All this was proposed centuries ago purely by observations.
Think of a piece of caramel being moved outwards
along its length, necking occures and bingo you have the other vector pushing in from the sides.
When Newton stated every action has an equal and opposite reaction he was not thinking of a singular force or vectors but of two.
The two vectors can be seen in action when caramel is being pulled.
You have an equal force
as a reaction to the initial pull and you also have another vector generated on the other or opposite side of the caramel that creates the necking or thinning where opposite in OLDE ENGLISH terms
was a 90 degree change in direction and not one that is actually opposing the initial vector.
This approach is the same as that of Einstein with the STANDARD MODEL which eventually comes down to just the combined action of the said two vectors which again supports the action of a ground wave between two mediums. Maxwell pointed to the same thing when he recognized that is law on radiation required a second vector(displacement current) which finally put the mathematical expression into the "must have" requirement of EQUILIBRIUM. Now both supporters of the AETHER and its deniers can be satisfied by labeling the particle carpet as the missing medium, which by the way was identified by Gauss with his laws on static particles. So Cecil
is quite correct on his explanation of quantum soup
which in itself is not a medium as required by the two vector system but by the identification of the missing medium which is the carpet layer from the Galaxy resting as a mantel upon Earth.
Regards
Art

John
We now come down to the question as to whether the two vector
explanation is of any use by applying it to antennas.

Let me come back to the double helix or the "genome" of life
Science views a coil as a load with respect to antennas or a dummy load again with respect to radiators. We all know that a coil can be made where it is totally resistive and completly absent of reactive forces because with the about turn of direction of current flow stops the formation of both
capacitive and inductive vectors.
When the current flows thru the coil tradition points to science as seeing this as the metallic resistance
of say aluminum. This is false in that the resistance
seen is the resistance to the skin depth anomally
created by the foot hold of a external magnetic field.
In this case there cannot be an external magnetic field ie no reactances and therefore no skin resistance. Now it is this resistance that was keeping current flow from rising to the SURFACE
of the radiator such that the radiator is not now the path that the current takes which is now BETWEEN the two mediums such that its two vectors direct current and displacement current can devote itself to purely producing radiation by ejection of particles with spin. So in other words
the external magnetic field by creating skin depth is the worst enemy of radiation which is the creation
of a wastefull friction component. Removing that magnetic field is the same as what superconductors do except in radiation current flow by passes the subject mass regardess of its resident friction where as a superconductor actually reduces the mass friction instead of by passing it.
When applying this to computor program the radiation patter evolves into two separate patterns merged into one wher the axis reflects the two vectors of gravity and rotation.
As a side note the radiatin member is never totally devoid of resistance ans it now takes on a vibratory action from the levitating vector on its surface, so ohms law stays intact by virtue of the change over to pendulum mathermatics

So John we now get to the final portion that closes the loop with
respect to radiation. The method of winding the coil is similar to a
solenoid without the central plunger. Around a solenoid is a shield to
retain the external magnetic field. This very arrangement is exactly
that of a Faraday shield but with two openings top and bottom and the
Faraday shield has the unique property of separating electric,magnetic
and time varying current into separate parts such that it is in effect
both a transmitter and receiver where as lternating current can be
used to form a tank circuit or alternatively
separate the time varying current back to drive a receiver. So the
same as what is required for a Faraday shield is also required for a

radiater which is a bleed line between the outside of the shield to ground to remove static from the system. If one puts the solenoid or Faraday shield over a
reflsector then we have two patterns each on a separate axis but superimposed upon each other where the center plume relates to gravity.
The above in no way violates existing laws for electrical components and in fact support those in existence made by the Masters. All the above enfolded by reviewing existing laws and expanding
thbe Gaussian static laws into dynamic form as the leader in the resulting trail. Remember a vertical antenna must be tipped with respect to Earth to reflect two vectors so it attains equilibrium.
Regards
Art Unwin KB9MZ.....xg
then one has a directional antenna which has two

Yes, it was a nice description ...

Uh, huh, so that is what "... created man in Gods' image ..." means, the double helix! I'll be looking for one descending from Heaven soon!

Keep up the good work,
stiff lip and all that,
regards,
JS

Art,

You waste your words on me. I will only cop to a few things:

1) I believe the ether is real and it exists about us, in us, everywhere.
2) All our "real matter" was ripped from the ether and is just ether existing in an altered state, "this all" is not "normal."
3) Although we can't "see" the ether (yet), we can make guesses from its' apparent properties. One important one, it is a superconductor. EMF can, apparently, transverse it forever with no "loss" (some will mention a "red shift", or "slowing", here.)
4) "Discovering" it will boost our economy, flood our markets with uncountable new devices exploiting its' properties and raise mans' scientific knowledge to unfathomable heights ...

Beyond that? Who knows ... I think, at this time, your ramblings are just as valid as any I could make, about it, the ether ... since yours sounds so "crazy", I hesitate to go into such depths ... sorry ... remember, "fools" (well, Einstein did) run where brave men fear to go ...

The "double helix", as it involves antennas, is only a trick to me. And, use to coax certain actions/behaviors from an antenna. It is physical in existence and can affect antenna fields and other properties ... it is no more profound or magical than a gamma match, capacitive hat, etc., sorry ... at this point, this is all I want to know.

Regards,
JS

John We live in a World that is not of our making.
It is us who search for the release of energy from that around us so
we can live the life we live. We have used electricity to create light
we did not generate the initial supply. Same goes for oil gas and wind
which uses the same two vectors supplied to us. But these energy

supplies are not enough to sustain the future and science cannot produce new energy only to understand what is around us so that we can then make the most of it.
Yes we use magnetic power to move friction to conserve energy by levitation and what goes with that knowledge is the solenoid that really is a double acting single cylinder that converts knowledge of what we know into energy. The windmill uses the two vectors of the weather straight and rotational and we know what the energy does there. Now we have a faulty electrical grid system that must be replaced and ideally Ac current is best for that but for the losses. Now I point to a way of bypassing those same losses, a new ladder to climb. By the way if you decide to make the antenna put a 20db anttennuator in the line first to avoid destruction of the front end. When I first connected up to 10 meters it wasn't open but the meter shot over S9 forcing me to shut down quickly. When experiments with superconductors for antennas 20 db improvement was noticed so one has to be careful. A MRI can project a personal object being worn by a patient
out of his clothing and thru a substantial wall so tread carefully. Remember a lightning strike is nothing more than the static energy of a particle seeking a place on Earth that it can rest after losing its resting space created by updraft and temperature change. We know the energy is there
the trick is to harness it.

John
If we follow the pied piper on a well trodden trail then education is
plagerism at its worst.
Being like Jack with the bean stalk means curiousity leads you on a
path that is not well trodden but produces surprises and new vistas
never seen by man!
Heh I like how that sounds, very profound.

Art,

You play to the choir.

Everyone who has found something new, has first had to surmount and defeat ridicule and/or worse, before all claim him to be a genius. But, doing such, surmounting/defeating ridicule, does not guarantee finding something new.

There are many more men sitting in "nut houses", and "searching," than there are discoveries to be made ... a wise man would tread the grounds cautiously, as I have mentioned ... LOL

John the question you raise with regard to the tank circuit is very
valid. But when a superconductor is used as a radiator removal of the
time varying current is consumed by losses
Let me propose the following, presently it is assumed that the super
conductor resistance goes to zero which embraces perpetual motion if
losses disappear. What if the current rose to the surface
like my antenna which is determined as the "Meissner effect". The

material is being bypassed
and replaced in the circuit by resistance traveling along the surface
which gives you the analogy of the long pendulum. One has to be wary
of embracing perpetual motion as in itself it destroys all we have
determined in physics.

3721. If you are a believer..

After Jesus "died" he appeared three days later where he spoke to Mary Madelyn.
He had to caution Mary not to touch him as he had not yet prepared himself to levitate into the heavens. This was akin to changing himself into water such as with a frog that scientists have shown to be levitated and life has shown the appearance of fish and frogs in roads miles away from ponds after a storm. Something to ponder over.

No John I am not jewish! But there are other instances as per the
parting or updraft of the Red sea which later came back down to reseal
the path.
I am not making this up as it was written well before I came along but
there is some similarity even tho I cannot explain it. One thing that
was also written at the time that only a few jewish people continued
on the journey while the majority
stayed enjoying their former bad ways. These were not receipients of
the "promise" so what is going to happen to them when they lose out on
judgement day?

OK. Since the real Art Artstein has been missing for quite sometime, and
has been replaced with a cleaver alien clone ... it leaves me no choice
other than to involve the authorities in this.

Will the real Art Artstein please stand up? Else, you give me no
recourse! <straight faced>

Roy:

My post showing very high input SWR at the base of an unloaded, base-driven, 10 foot vertical on 3.8 MHz described an UNMATCHED system resulting from its connection to transmission lines of typical impedance values. It did not include matching networks, whether located at the base of the vertical radiator, the output connector of the transmitter, or wherever.

Then you posted, "Using your antenna as an example, suppose that a transmitter with output Z of 50 ohms is connected to a tuner that transforms its output impedance to 0.6 + j1250 ohms. ... The transmitter will see 50 + j0 ohms, the antenna will see an impedance of 0.6 + j1250 ohms, and full power will be transferred."

That configuration you posted is a MATCHED system, and its performance does not disprove the accuracy of my post.

So you're saying that the mismatch between the impedance of an antenna and the transmission line connected to it doesn't inhibit power flow when there's a matching network anywhere in the system. But it does interfere with power flow when there's no matching network?

What if the antenna is 50 ohms and the transmission line is a half wavelength of 600 ohms, for a 12:1 mismatch? There's no matching network. The transmitter sees 50 ohms. The antenna sees 50 ohms. What will interfere with the power flow?

This, and your other what ifs describe a system *different* than the
one in my post.

The performance of the systems you described does not apply to the
system I described, and vise-versa..

I've definitely gotten lines of various sizes stuck in tree crotches
if left unmoved for an extended time.

I have been advised, (but have not take the advice!) that running the
rope through a garden hose, which is sitting in the crotch, is the way
to prevent this from happening.

If I were climbing the tree to get the line up there, that'd be easy
enough to do, but using a cannon to send the line over it's not so
obvious. I'm thinking right now, with my 1/4" rope, that maybe I could
use the rope to pull a hose (not as thick as a garden hose maybe) up
itself.

John he doesn't bother me. The more he posts the more people
understand what a child he is.
Soon somebody will go to a modeling program and try it out and it will
all be over. I am not fully familiar
with Eznec but I understand it already has a sample
of a coil which makes it easy to duplicate to try out above UHF. A
condensed antenna with extremely high gain is very desirable to the
ham community and elsewhere so interest will win over in the end.
Thanks anyway for the support, you can't be an engineer for very long
if the bridges you build keep falling down and I worked as a senior
engineer with G.E. for most of my life so I have walked the walk.
I forgot to mention that this antenna does not have a formal bandwidth
as it is resonant on all frequencies up to the length of wire used for
the lowest frequency.As the wire only carries a minimum of current it
can be quite thin and resistance is so small it is not a problem to
use
loads of wire and still maintain a condensed antenna. Mine is light
enough to hold up with one hand and place it in the rotor on the tower
top and is good down to top band. Sounds crazy but I have provided the
physics which is supported by my actual antennas as well as the
computer programs.
Regards
Art

I had some spare time today, to just let my mind wander. You know how mooselums must face mecca each day? I wonder if moohamad ever gave any advise what direction mooselums should face their antenna? A sloper, facing mecca would seem to be suitable; Indeed, the antenna would almost be in a "praying conformation!" I mean, surely, no fault could be found with a mooselum utilizing one of those babies!

You ever given much thought to that?

Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.
```

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

Apparently, tree climbers use a wide strap called a "cambium saver" to protect the bark and allow lines to run freely. The following link shows how it may be positioned in the crotch of a branch, and even retrieved after use, working only from ground level:

<http://www.instructables.com/id/How-to-get-a-rope-into-a-tree-without-climbing-it/>

Roy, you may have a chance to try this, sooner than you think!

In my simplistic world, this is how I understand things:

Provided the TX is followed by a tuner/matcher, which matches whatever
is attached to the tuner output to 50 ohms at the tuner input, the TX

will be happy.

The power loss in the feeder is essentially a function of its inherent loss (when matched) per unit length, and the SWR on it.

The SWR is a function of the mismatch between the load on the antenna end of the feeder, and the feeder characteristic impedance. The greater the SWR and the longer the feeder, the higher will be the loss on the feeder. 'Lossless' feeder have no loss, regardless of length and SWR. However, with real-world feeders, the losses rise increasingly rapidly with increasing SWR.

The impedance looking into the tuner end of the feeder is the impedance of the load, transformed by length of the feeder, and is also modified by the loss of the feeder.

The higher the feeder loss, the closer the impedance seen at the tuner end will approach the characteristic impedance of the feeder. [Long lengths of lossy feeder - maybe with a nominal termination on the far end - can make good dummy loads at VHF and UHF.]

Wrong.

>

Well, the SWR at the load end is a function of Zl and Zo (both complex
quantities)... but the 'notional' SWR varies along the line as accounted
for by the complex propagation coefficient, in most practical cases at
HF, SWR decreases smoothly from load to source.

See your earlier misconception regarding loss being a simple function of
SWR.

Yes, but is it of practical application in a transmit scenario? If the input impedance due to a severly mismatched load is at all close to Zo, then you have lost most of the transmitter power in the line.

The "make a good dummy load" recipe doesn't address the power rating, especially where most of the power is dissipated in a very short length of cable.

Owen

How did that e get in there...

"Happy", a new dumbed down attribute of a transmitter. Everyone loves a happy transmittter.

What happens if they are not happy? Well, everyone knows you will let the smoke out of them (AKA reflected power is dissipated in the PA and kills transmitters).

Yep, a simple world... even if wrong.

That's the result of the 50 ohm Z0-match achieved at the input of the
tuner which is responsible for the transmitter's "happiness". A Z0-
match causes the incident reflected energy to be redistributed back
toward the antenna through a combination of reflection and destructive
interference.

This may have changed also, I'm no expert in superconductors (though I do play one on TV) Don't the high temperature superconductors have issues with current capacity, and does this translate into problems with impedance?

Sorry, missed this earlier, must have hit, "mark newsgroup as read" a bit prematurely ...

Well, just guessing, I'd say, it came from the "immaculate conception", and Mary contributed ... but hey, mankinds DNA came form God ... I find it a much better question to ask, "Is God a "true God" or an alien, or alien race?"; And, "Would I be able to tell the difference if I ran into either?" And then, there is the question, "Where did God/alien-race come from?"

It ain't easy being human ...

Oh, indeed. But I have to confess that I've realised that I'm suddenly
unsure of where, on a long, lossy, feeder with a mismatched load, most
of the absolute power is actually lost. I'm assuming that it is at the
TX end, where the power is greatest - even though that's where the SWR
is best. Please advise!

It seems logical that the highest I^2*R losses would be where the
standing-wave current is maximum and the highest dielectric losses
wold be where the the standing-wave voltage is maximum. As Owen is
fond of pointing out, the locations of those points are very
important. If a current maximum point exists at the load and a voltage
maximum point exists at the source, the losses at the load are
probably higher than the losses at the source on HF. If a voltage
maximum point exists at the load and a current maximum point exists at
the source, the losses at the load are probably lower than the losses
at the source on HF (assuming that losses due to SWR are mostly I^2*R
losses on HF).

Uhhh, sorry to pose this question to you here but, doesn't a "tuner"
really just "shorten" and "lengthen" the feed line? I mean, not
physically, of course. But, it would seem to me that, this is exactly
what my xmitter and ant are "seeing."

If all the tuner did was shorten and lengthen the feedline, there would be only one purely resistive low resistance available on the SWR circle on the Smith Chart and it wouldn't be exactly 50 ohms. So a tuner does one other thing - it transforms the non-50 ohm resistive impedance to a 50 ohm resistive impedance. It is not only the equivalent of shortening and lengthening the transmission line but also performs an N:1 transformer function. Of course, it does that seamlessly, i.e. it is not actually a two-step process.

When I vary the length of my ladder-line to obtain system resonance, I have to be satisfied with purely resistive impedances between 35 ohms and 85 ohms. I cannot achieve a perfect 50 ohms on all HF bands with my matching method. That would require the addition of an actual N:1 transformer which is certainly possible but probably not worth the effort. Since 35-85 ohms is perfectly acceptable to my SC-500 amp, I don't need a high-power tuner. And since the SC-500 is spec'ed to handle an SWR of 6:1, I doubt that an 35-85 ohm load makes it "unhappy". If my SC-500 has ever been "unhappy", I failed to observe that "unhappiness" but maybe I am just oblivious to such? :)

Hi Mike,

High temperature is a relative thing (being it is measured in the 10s
of Kelvins for high temperature superconductivity).

However, Impedance? In the convetional application here in this
forum, it is a remote consideration for research. Afterall, nothing
has changed about the usual characterisitics of conduction,
inductance, or capacitance except for conduction's magnitude/density.

Aside from the conventional discussion here, researchers do tons of
work in the realm of superconductivity that employs radiation. That
body of research is called Plasmonics and Excitonics. Phononics
doesn't strictly apply because it is, by definition, high temperature.

Most of the research into subresonant structures is done in the
nanoscale. What is discussed here as possibilities in that same
regard is sheer nonsense. However, there have been glimmers of
nanoscale research reaching out into the macro dimension.

I've posted such items from Boeing's skunk works on negative
refractive index material research. It is something that could be
modeled in NEC - but only at a vastly expansive scale with hours of

computer time to run.

I am going to broach a taboo and see if an attachment of a split-ring resonator would be supported.

The SWR on a feeder will always be greatest at the load end. However,
because of the feeder losses, the power will also be lowest at the load
end.

So, although the power loss per unit length (in dB) due to SWR will
steadily increase as you approach the load end, because of the feeder
loss, there will be less absolute power (in watts) to lose as you
approach the load end.

The question is, at which end of the feeder is the most absolute power
lost per unit length?

I already explained that. On HF, maximum losses depend upon where the current/voltage-nodes/loops are located on the transmission line. One cannot answer the above question without knowing that information and the answer is different depending upon the conditions.

Owen has previously proved that on HF, a higher SWR can result in lower losses than a flat line when that high SWR is near a current node and the feedline is less than a quarter wavelength long simply because the average standing-wave current is *lower* than the flat line current.

Ah, I see what you mean. I was thinking in terms of an 'electrically
long' feeder (many wavelengths long).

I can see that, for a 'short' feeder (for example, if you were feeding a
halfwave dipole via a quarterwave of 300 ohm line), at the antenna
feedpoint you will have a current node (high I^2*R loss), and at the
TX/tuner end, where there is a voltage node, you will have a low I^2*R
loss. It could be that the loss of a matched relatively low-impedance
feeder of 50 or 75 ohms (being inherently higher than that of higher
impedance feeders with similar conductors etc) could be higher than the
average loss of the 300 ohm - even though the antenna will present an
SWR to the feeder of around 4 or 6 to 1.

That still leaves the question of which end of a long feeder has the
greater absolute power loss. Using 'reductio ad absurdum' and 'rule of
thumb' (two very dangerous principles!), I feel that it can only be at
the TX end. If the cable is really long, any power left to be dissipated
at the load end must be negligible compared with that available at the
TX end.

In response to your two posts...

You might be informed of the traditional graphs (or simple underlying formulas) of "Additional loss due to VSWR" that appear in some publications including several ARRL publications.

The formulas on which these graphs usually depend rely on a set of assumptions that are often, if not usually, not stated.

You could be forgiven for interpreting these things to mean that loss per unit length (in dB) is constant along a transmission line independent of VSWR.

The traditional RLGC model of a transmission line does give constant loss per unit length when VSWR=1.

For most practical lines at HF, most of the loss is due to conductor loss (the R term in RLGC) and very little due to dielectric loss (G in RLGC). The result of that is that line loss in any incremental length is very dependent on current, higher in regions of higher current, and lower in regions of lower current.

Consider the loss in 1m of RG58 at 3.5MHz with a 500+j0 load. It is a very short line electrically so current is almost uniform. VSWR=10 and current is approximately 1/3 of that for a matched line for the same transferred power.

Why should loss be greater than a matched line when I^2 is one tenth the matched line case? Well, it isn't. The formulas and graphs do not apply because the (often unstated) underlying assumptions are not met.

Regarding the dummy load, it might seem intuitive that loss is highest where the VSWR is worst, but that is not correct. The correct answer is found by calculating the loss along the line.

If you consider the case of 100m of RG58C/U with O/C termination as a dummy load for 1296MHz...

Lets section the 100m into 10+90m.

Using TLLC (http://www.vk1od.net/calc/tl/tllc.php), the input impedance of the last 90m is 50.00-j0.01.

Now lets look at the first 10m of our 100m, it has a termination of 50.00-j0.01 and the loss is 8.5dB, only 14% of the input power flows into the last 90m, 86% if the input power is lost somewhere in the first 10m.

By the same method, you could find that almost 20% of input power is loss in the first metre, even though the VSWR in that section is almost perfect.

Well, engineering of lightning protection is about design of a protection system that will, amongst other things, survive most events so as to continue to provide protection, and to minimise incidental damage.

So, yes, down conductors adequately sized to manage the risk of the conductor "vapourising" is part of the scope, and physical design to minimise the risk of side flash causing damage is also part of the scope.

It is interesting, no confusing, that you have two guides that give such different guidance. In Australia, we too have a standard for house wiring, and another standard for lightning protection, but they are not in conflict and our standard for lightning protection is well aligned with NFPA 780 on the downconductor size issue.

That is indeed very interesting - and illuminating. I've always assumed that, for electrically long feeders, most of the power got lost at the input end - but I didn't realise that the effect was so dramatic. I must do a few calculations for myself!

And as for electrically short feeders, I do see how the greatest power loss is where there are current nodes etc (although, presumably, averaged over a halfwavelength, the power loss will still be greater towards the TX end). But I now recall that some time ago, there was a lengthy discussion (in this NG, I'm sure) about how a matched low-impedance feeder could actually have more loss than a mismatched relatively high-impedance feeder.

I chose a case that would be clear. When the line loss is low, it is not
so dramatic. Trying to find Rules of Thumb in all of this is fraught
with problems.

Well, if you do some calcs yourself, what you learn will stick in your
mind. Just be sure that your study is reasonably comprehensive so you
don't come away with some new, but flawed, Rules of Thumb (RoT).

You could persue the dummy load example a little further. How long does
the line need to be for VSWR<1.1, and if the continuous dissipation
limit of RG58 is say 6W/m, what is the continuous power rating?

Owen

The thing is, AWG 6 wire won't vaporize or even melt or even get warm to the touch. There's not enough "action" (I^2 T) in a lightning stroke to do it. Remember that the current is high, but only lasts a matter of a 50-100 microseconds.

Say you are using AWG 10 wire which has a resistance of 1 milliohm per foot. a 50 kA strike will dissipate 50E3^2*1E-3 = 2.5 MegaWatts.. which is big.. but for 50 microseconds, that's only 150 joules. That same foot of wire weighs about 1/2 an ounce (I'm sorry for the customary units, but they are what I remember off the top of my head AWG 10 is 1/10th inch in diameter, 1 ohm/kft, and 32 ft/lb).. or about 14 grams.

Specific heat of copper is 0.38, so we have deltaT = 150/14 * 0.38 let's call it about 4 degrees C.

I should note that this is a bit optimistic.. the AC resistance for a 50 microsecond pulse will be higher than for DC because of skin effect (skin depth at 1 MHz is 65 microns, 2.5E-3 inches, and it goes as the square root, so even at 100kHz, it's still not much more).. so the dissipation will be higher.

But, you've got a long ways from 30C to 1000C (melting point of copper) and even farther to "vaporization"...

(as a practical matter, you need kiloJoules to explode a 1 meter AWG 30 copper wire.. hundreds of joules just "melts" it.)

(note also that while the peak current might be 50kA or 100kA, the average current is substantially less..)

Mechanical stresses from magnetic fields are a bigger concern, as well as "sideflash".

Even then, the same principle applies, at least on HF. If the standing wave current maximum point is located near the load and the standing wave current minimum is located near the source, the maximum transmission line losses due to SWR will be near the load. If one reverses those conditions, the results will reverse. As Owen suggests, plot a graph of I^2 along the line - pick your particular load point and particular source point and almost any outcome is possible.

Cecil,

As you have presented this argument in the past, it cannot either be proven, nor dis-proven--and must be considered.

If it were not for the fact that life is the sole "thing" which possesses such unique qualities as to behave as something from a conscious mind, something requiring more than nature to create it, requiring more than accident to have achieved its' present state, I'd have to give what you present much more weight. We must agree that "things" look different to us, at least on this one subject.

As I stated, in slight different words, it is H*LL to be human ...

Regards,
JS

Well, that's not a problem anymore. My dog killed him a couple months
ago. It was an accident. And even if it wasn't, after you've seen your
dog kill Cthulhu what is there left to fear?

At the transmitter end. Suppose you have a 100 watt transmitter and a
cable with 3 dB loss per 100 feet.

50 watts is lost in the first 100 feet
25 watts is lost in the next 100 feet
12.5 watts is lost in the next 100 feet

and so forth. If you were to divide this up more finely and plot it,
you'd find an exponential decay of watts loss per unit length versus
distance from the transmitter.

You might find Fig 10 at
http://vk1od.net/transmissionline/VSWR/displacement.htm interesting. It
is a plot of the power along a length of mismatched line.

The plot doesn't answer your question directly, but the slope of the line
in Fig 10 is the answer to your question for the scenario modelled. The
slope is steepest around the current maximum nearest the source.

Fig 9 is interesting as it shows the loss for a mismatched line can dip
below the loss line for VSWR=1.

The thing that becomes apparent from Fig 9 is that the common practice of
doubling loss for double the line length works for the VSWR=1 case, but
not for the general case. As a mismatched line is lengthed, the
increased loss for each *extra* metre of length *approaches* the
matched line loss and the line length approaches infinity.

Sorta. The old testament says (somewhere) that about 600,000 left
Egypt. No clue how many followed Moses into the desert as most just
wanted to leave the scene of the disaster (10 plagues). 40 years
later, about 25,000 entered the promised land with Joshua. Most of
the 40 years was probably spend building and training an army, so
there must have been a major reduction in followers in the desert. The
actual numbers are highly debatable.

As for "bad ways", that's also debatable. For example, what's the
difference between a bribe and a commission? The only difference is
when it's paid. A bribe in advance, a commission after. In most
middle east cultures, bribes are necessary to secure ones profit.
Anyone taking a commission is usually deemed a fool. Yet, western
culture defines taking a bribe as evil, and a commission as desirable.
So, who's acting badly, and from who's perspective?

>These were not receipients of
>the "promise" so what is going to happen to them when they lose out on
>judgement day?

Same as what we do today.... bribe the judge and pay off his cronies.

Hmmm
Then it would appear that the promised land was only given to less
than 10% of those that left in the first place! Maybe Gaza will be

large enough for those that followed thru. Grin. I would imagine that decimation could avoid that strip of coastal area.
Maybe agreement will come after all, but not this or the next time around as Israel has not stopped gaining ground.

Well, it does take a bit more than a farthing, but it's still
possible:
"Israel's biggest lottery winner claims prize after 4 months"
<http://www.haaretz.com/news/israel-s-biggest-lottery-winner-claims-prize-after-4-months-1
.284172>

After crossing the Red Sea, the next step was to setup an antenna and
make some contacts on the other side, which would certainly have
qualified as a new country. Not having any wire antennas handy, we
used the next best thing:
"Sea Water Antenna"

We claimed abandonment by the other interested parties.

While enforcing a 3000 year old land claim might seem a bit odd, we do have some of the best documented evidence (i.e. the Old and New Testaments) which have stood up in the courts for at least 2000 years. The only problems have been when deconstructionist academics and movie producers attempt to reverse engineer the intent of God. This might have succeeded had they been successful at issuing a subpoena asking for explanations and corroboration of the land claim.

>Maybe Gaza will be
>large enough for those that followed thru. Grin. I would imagine that

Decimation means 1 out of 10. That's been deemed politically inexpedient after the Romans tried it, and found it useless. These days, we just build a wall down the center of the country.

>Maybe agreement will come after all, but not this or the next time
>around as Israel has not stopped gaining ground.

Agreement has always been easy. Keeping the agreements has been the main problem. It isn't just the Arabs. We have the same problem. Get 10 Jews together to form a minion, and instead of agreement, we have an argument. It's a miracle that we've gotten this far, being so screwed up, but that's just evidence that God is on our side.

The losses and problems with that will keep a tinkerer quite happy for a lifetime. Reminds me of an old antenna I seen which used a thick quartz tube and was filled to appropriate heights to tune resonance. Was very interesting, and a fun toy for the owner, but I am waiting to see it in mass production.

For some, no proof in possible, even with YouTube videos.

Let's pretend you just marched across the Red Sea, on sea urchin and
coral encrusted sandals. You follow Moses until you get to Mt Sinai.
The boss then disappears up the mountain, and comes back with some
rather draconian rules and regulations. He then grabs all the metal
he can find and uses it to build the Ark of the Covenant, which was
suppose to be some kind of transmitter to talk to God or perhaps
aliens in their flying saucers. With all the metal used, what do you
use for an antenna? Of course, salt water.... and you wonder why part
of the Passover ritual is dipping just about everything into salt
water.
<http://en.wikipedia.org/wiki/Ark_of_the_Covenant>
God was said to have communicated with Moses "from between
the two cherubim" on the Ark's cover (Exodus 25:22).
One theory has it that the Ark was an arc lamp, which is close enough
to a spark gap xmitter to qualify as a transmitter:
<http://einhornpress.com/holyark.aspx>

Ok, let's forget the salt water antenna. Maybe an inflatable antenna
would be more practical. An inflatable antenna certainly would be
more useful for getting cell phone coverage for the multitudes in the
middle of the desert:
<http://www.youtube.com/user/ltaprojects#p/u>
<http://towers.ltaprojects.com/LTA_Towers/LTA_Tower_Home.html>
(formerly Bosch Aerospace). Can you hear me now?

Looking into the modern theories of Aether, your statement is correct.

The problem I have with the new Aether theories is that they take the intellectually inexpensive leap from science to something else.

Quote from Wikipedia

"John Bell suggests the aether was wrongly rejected on purely philosophical grounds: "what is unobservable does not exist""

By which this time, we might as well fold the tents and go back to the easy answer, because if we take that tack we already have all the answers for everything in the universe.

There's an old New Yorker cartoon with a couple of scientists standing at a blackboard. The blackboard is covered with aequations, and right in the middle of them in paren is "And something really awesome happens", folled by more equations. That to me is Aether theory.

Might as well just say the answer is because God wants it that way.

On TV news last night they showed a video of a police officer talking
to a man resting on a sofa in his own home. His wife had called
saying that he had a heart attack and should go to hospital. The man
refused to go
preferring to rest rather than go to hospital for treatment as he
could not afford it. The police officer then tazered him to make him
go to hospital! The chief of Police said that standard protocol had
been followed.
Only in America!!!!
I wonder if he is still married to the woman
or he cancelled his insurance policy?

A "leap of faith" is required for a belief in God, the beginning of a religion. So, to me, most atheists look "religious" to me. Their religion is akin to having two men walking along in some far flung universe when they stumble upon a man-made car. The appraise it, toy with it, climb in and take off.

Now, down the road, one man says to the other, This appears as if it was made by god," the other mans says, "That is ridiculous, this obviously evolved from the elements around, and simply natural laws seen to its' creation."

The whole universe, everything we see, I must wonder if "it always was." Or, if a thinking mind constructed it all, even down to constructing the laws for it to exist in, then the bizarre question of my own existence enters this wonderment. It is easy to say that the ether was, is and always will be--we are born into it.

Atheists just have an easy way of accepting things. They look at all of this/these "MIND-BLOWING MIRACLES", and just say, "Oh yeah, it is natural for all this to exist, there is no such thing as an "absolute nothing", it is a law that if you universe sized space, it is filled with matter in an altered state from the ether."

And, even worse than that, many can't/don't even recognize an ether for the matter to have been created from and exist within. I do admit, my mind finds such simple acceptance shocking ...

Art,

Was he holding an antenna?

Anyway, if I'd been present, I would have been arrested. I would have considered force, up to the point and including lethal, would have been justified in stopping such a revolting display. Somehow, tazing an ill man having, apparently, a heart attack/pains puts that individual preforming the action below chit, in my world ... sad, so very, very sad ... it is why the wife and I are considering a move to Montana; I just hate the cold.

Non jews in Israel will never accept expulsion to the
new palestinian State in Gaza so that the land of Israel can be
totally segregated and jewish. Yet until that happens the opening of
the heavens cannot happen without involving the destruction of non
jews!
A predicament has been written!

I'm sure it was all done with the best intentions. What probably
happened was that the police officer suspected that the husband's heart
rhythms had gone all twitchy, and he needed to apply a spot of instant
defibrillation to save his life.

But rest assured that this sort of thing doesn't only happen in America.
In the UK, where the police still, for the most part, do not carry
firearms, they now carry a veritable arsenal of supposedly non-lethal
devices (including tasers). While these are only supposed to be used as
a last resort, when a miscreant cannot be subdued by the more
traditional methods, they are increasingly being used, as in America, to
ensure instant compliance.

You are confused, again, Art. The promise was to the Hebrew people,
not the "Jews". Very few of the "Jews" in Israel today are Hebrew.

Paul

AFTERMATH.
The judge dismissed charges against the police officer after being
shown police rules that recipients of a tazer gun MUST be taken to
hospital prior to internment.
The same judge dismissed divorce proceedings stating irreconcilable
differences had not been proven and the husband was to pay all court
costs.
The above part anticipates what is yet to happen.

Yeah, may even be looking at our next president, the cop.

That kind of judgment, logic and actions seem popular with our
criminal/treasonous public servants, these days ...

Well, I did jump to a conclusion, based on insufficient data.

This cops' heart might have been in the right place. He needs a caution given to him and partnered with a more level headed officer. He may actually have what the public wants/needs ...

It speaks horribly of Amerika though, we need a "kinder/gentler" way of providing assistance to those unable to afford it ...

AFTER AFTERMATH
The husband on hearing the judge speak fell to the ground gasping and
clutching his chest. He was taken to hospital with his wife by his
side and who stayed at his bedside where further enquires listed his
condition as ..."grave".

Did he have an antenna in his hand in the courtroom? Did anyone mistake
it for a weapon? Was it a loaded antenna?

Art, supply all the data so we can make proper statements!

Heh, this group is so full of negativety and poor judgement so I
thought that Katie Curic news story
yesterday should be jollied up a bit, so that instead of laughing at
others we should try being the recipient to see if our actions hurts
others.
Have a great week end.

No. I turned the "truth" into a "joke". The same as others did with my
antenna design where they turned it into a massive joke so that they
could apply judgement with a lazer for laughs and nothing being meant
to hurt me as a person.
Lets move on

we don't have to turn your design into a joke, it starts that way and
you try to pretend its the truth.

Seriously, though, the real question is "Where did the ether come from?" (and, everything else which is composed of it.) You can see how far we are from even being able to pose that question; We have to "discover it" first. It is actually a little premature to be having intelligent conversations, debates, discussions, etc. until there is something to have them about!

Excellent article. States my premise well, especially:

"Because there is a law such as gravity, the universe can and will
create itself from nothing," the professor said in his new book, in a
challenge to traditional religious beliefs.

I am aware of no such proofs of such a law; And, Hawkings only presents
another religion for us to join-- "The Order of the Law of Spontaneous
Creation."

Don't need more religions, need answers here. Don't need to convert
science to a "football game" where you choose your side and root for it
... Hawkings proposes I make a leap of faith not even I can stomach ...

Ian,

I am not making light of the reality of bad judgment, and the seeming explosion of it recently. These situations and the efforts being applied by our public servants, from the president on down, I follow closely ... frequently in utter amazement.

I am just having a bit of fun, as I am sure you were and even Art is, in his own way.

Regards,
JS

John. Some are looking for an explanation for the existance of the
horizontal vector between two mediums. I do not know the originality
of that particular finding. I do know that a horizontal vector exists
in radio ie surface wave. Naturally some scientists would want to know
the other medium that allows this to happen and others have not
provided an explanation, so there is scientific reasoning on both
sides
Now Art came along and expanded Gaussian static law to make it dynamic
and equal to Maxwells equations on radiation. Thus was established the
presence of galactic particles resting on all diamagnetic surfaces on
earth, bearing in mind that diamagnetic material composes 99% as well
as the mantle of Earth of Earth (Bismuth). Now that I have described
the other "medium" in question I will leave it to scientists to
determine and understand the questions arising from the double slit

experiment
which in these days of denial may take another 100 years. Remember,
the presence of particles is well established outside classical
physics and partical physics and now we can all agree that what can be
accellerated must consist of mass.
This thus dismisses the silliness of radiation being created by a wave
which is only an adjective decribing the movement of same in
abundance.
Like the "o" ring in the space vehicle scientists deride what
engineers accept as normal.

Apparently, human intelligence and logic has not yet evolved to be able to handle such questions although Ayn Rand came close decades ago.

John, since you asked that question about what caused the ether, you obviously must believe in the principle of "first cause", i.e. everything has to have a cause. To avoid being a hypocrite, you must also asked yourself, "What caused God?" - and what caused the cause of God? - and what caused the cause of the cause of God? ... ad infinitum.

I suspect Hawking is thinking: If everything has to have a cause, what caused God? And if God doesn't need to have a cause, then why does the cause of the Big Bang need to have a cause?

Yes, yes I do see cause and effect--in everything which is real ... indeed, if someone comes up with an amazing story which leaves one out, cause or effect, I am highly suspicious. And, which I am of God, which, obviously, must exist!

As I have stated, I see nothing ordered, which is highly complex, unless a thinking mind has created it. When someone says, "Well, here, here is that "something" which breaks all the rules and it "just happened by accident" or it "just is, has been and always will be", I think, "They/he/she has to be kidding", even if Hawkings advances it. And, yes, logic dictates there must be one thing which did get "the ball rolling." That is God, whatever God is? If you want to make the ether God, well, great, let's explore that possibility. However, all anyone does is pose the "circular logic" which brings yours/mine/everyones mind back to the beginning and you must ask, "What is the God." Or, "What is the God event", etc.

It is un-win-able ... I suspect, better minds than Hawkings has pondered it down though the millennias.

Regards,
JS

But do you appreciate the first cause contradiction? What caused the first cause? e.g., what caused God?

I had an epiphany today. I realized why God is missing in action so much of the time. The Bible says that 1000 years in the life of God is like a day in the life of man. Man sleeps 1/3 of ever day. So God must sleep for 333 years out of every 1000 years. Bad things happen during the 333 years that God is asleep. Witness the present.

Well, first of all, I don't insist the bible be taken literally ... I do accept, that parts, i.e., Genesis for example, which happened before man could create written records. These stories had to be passed father to son, mother to daughter, etc. until mans ability to record these stories on non-verbal media came into existence. And, God sleeping? Naaa ...

Your first point points out why Hawkings seems to be "losing it," to me. He thinks everything began with the big bang ... the beginning was before then, it was when the ether came into existence, immediately raising the question, "Who/what created the ether?" And, perhaps the creator of the ether has a creator ... so, this is why I think we need to know more about the ether ... like I suggested, why even begin "making guesses" until you have enough data to make them intelligently? And, I over-emphasize that, of course, we may guess, but we need to remain honest and admit they are only ballpark guess on only the limited knowledge we now possess. Unfortunately, as you see, a guess can quickly become a religious order ...

So, to summarize, Hawkings is two steps ahead of creation (and God) already, he ignores, "Who created the ether?" and "Who created the ethers' creator?"

JS

Yes, very clever. When you only have a tazer at hand it probably is
a good choice. Over here one finds special-purpose electroshock devices
in many public places, and police officers often carry one in their car,
but not on their belt. So he must have figured the tazer was better
than nothing in this case.

"Before the Big Bang" is an oxymoron. Our present big bang originated
from a mass/energy plasma singularity. There was no ether in our
universe before the big bang. There was no space in our universe
before the big bang. There was no time in our universe before the big
bang. There were no particles or EM waves in our universe before the
big bang. Our present universe did not exist before the big bang.
Consider that our universe may have originated from a black hole that
exploded as it reached some critical mass/energy threshold and
detached itself from a parallel parent universe as it winked out of
existence in the parent universe. I use the geometric term,
"parallel", rather loosely simply to indicate that the multiple
universes never touch after the separation.

Always were the two ethers. Normal for the normal electric waves and the
"special" for the EM waves.

The normal is that by Ludwig Lorenz and the second by H. Lorentz.

The normal is the rare plazma (electrons, ions, atoms and dust).
The special is in many forms.

The normal is produced by the Sun. The special - I do not know.

Here we differ, I think the ether existed long before the "big bang" (indeed, it could be the was, is and has always been in God.) Whatever the big bang was, all it did was rip our observable matter, into an altered state, from the fabric of the ether itself, and we look back and record "the beginning" from that event.

>> There was no time in our universe before the big
> bang. There were no particles or EM waves in our universe before the
> big bang.

That statement is right on one account, there was not "time" in our universe ... but then, there still isn't. There is only movement ... I do believe the ether is composed of some type of particles, and I do believe the ether accounts for the transmission of our EM waves ... so I imagine that some type of "disturbances" were occurring in the ether, even before the big bang ... but, proofs, or disproofs, lie in the future ... I would drop everything and work to prove, or disprove, the ether ...

'normally' when something has to be called 'special' it means that it doesn't represent the real world... not 'special' relativity is just a subset of 'general' relativity. if the 'normal' is created by the sun and we now know that there is a discontinuity at the edge of the solar system where our solar wind is deflected by the galactic plasma... and indeed there are major discontinuities around the earth due to our magnetic field... why are there not distortions in the waves traveling in the plasma? if waves travel in water and the water is moving the waves move with the water, why can we not measure the difference in speed or direction of waves carried in the moving solar plasma, especially when it moves around planets with magnetic fields? why are light waves not affected by magnetic or electric fields??

Light waves (electromagnetic fields) are photons. Magnetic and
electric fields are also photons. Photons do not affect each other
unless they are coherent in which case interference can take place.
Photons have no rest mass and no charge. Any number of photons can
occupy the same "space". Photons are affected by the curvature of
space through which they travel.

In deep space, light should go 100% unimpeded by any magnetic fields.
In an atmosphere, plasma, or other media, I would think light can be
affected, fiber optics can even bend light using a physical force acting
on the media carrying the light, instead of a magnetic field.

In deep space, there is almost nothing but ether, and ether, the
gravitational ether of Einstein, needs to be bent with gravity, and when
the ether is bent, some distortion of the path of light should certainly
be detected ... but that debated experiment, someone already mentioned,
carries on.

It is getting close to winter times when decisions have to be made
for the seasonal antenna. My antenna is frequency independent with a
cavity / reflector and I have been feeding it via coax direct ie
unbalanced because of the constant impedance, therefore unbalanced to
balanced should not be a problem.
Anybody see an error in thinking here.
The antenna will be on a tower as the antenna picks up all
transmission modes so I need to get away from ground noise. I will be
adding an elevation changer if I have the time other wise it will be
parallel to ground or zero elevation.
Many thanks for your inputs
Art

In "deep space" are also stars so the electroms, ions, atoms and dust have
the different temperatures and density. Speed of all waves are the
temperature dependent. The refraction index also.

Hello John,

For me this is just a Guanella balun, 1:4 impedance transformation
with common mode suppression. I didn't do the math to see whether
common mode impedance is sufficient for OCF dipoles (to avoid feed
line radiation).

Regarding color use (purple/pink), that isn't limited to California
only.

Best regards,

Wim

At this point, I can't even remember why the reference of "balun to windom to Cecil" holds a relationship in my mind ... I didn't pay any attention to the core material/turns/etc. of the baluns which I posted either ... just seeing if it related to what has stuck in my mind and tossed it at Cecil to see.

The one I remember was about the Carolina Windom 4:1 voltage balun at
the feedpoint and the 1:1 choke-isolator 20' down the coax. The
original Windom was fed, Marconi style, against ground.

Let's call it "quantum ether" to distinguish it from the earlier
obsolete concepts. Yes, dark energy seems to make up ~70% of the
universe which is mostly space so there is little doubt that quantum
ether space is related to dark energy in some way.

Just throwing in my comments on the so called Carolina Windom like Cecil
described.
I have one up like that and also an 80 meter dipole and triband beam up to
compare signals with.
Not all cases, but many times the Windom is as good or better than the other
antennas. The beam does beat the Windom by about double the microvolt
signals on the very long signal path.

The balun I am using is suppose to be able to handle the power I am running,
but around 1 kw to the antenna the 4:1 balun overheats after about 5 minuets
and the swr starts going up. There is some current coming down the feedline
as the choke balun 20 feet down the coax is getting warm. It does not do
that with about 1200 watts going into it while connected to a dummy load.

Like most any simple antenna, you throw RF at it and hope the signal goes in
a direction that lets you make contacts. The antenna can be set so that it
is most favorable in one or two directions, but when making contacts all
around, it is difficult to change the direction of the dipole.

I was referring to the feed line. But since you brought up the antenna
I just noticed that it had only a portion of top band when resting on
the ground so I have to check it out on the tower before I move on.
Maybe just lifting it up a couple of feet will do the trick.
Eat your heart out dummy !

magnetic coupling to the stream seems kind of odd, but it appears to
work for him. i wonder what happens if you go qro? i would expect
some heating of the water and maybe even some ionization or corona
that might cause instability in the stream. i would also guess the
tuning would be difficult in high winds.

Hello John,

When the feed line goes to a clean environment (for example a ground provision far from the shack feed line radiation may not be a problem, but it isn't my favorite. When the feed line goes directly to the shack (and equipment), I don't want such an antenna.

When you are working NVIS on 75/80m, you don't want the vertical component as this leads to radiation under low elevation, hence stronger reception of ground based interference.

In case of DX, the vertical component may help you as this may result in lower elevation of main lobe; over here we have much soil with better then average conductivity. If I would like vertical polarization, I prefer 100% of that, so no windom or OCF dipoles for me.

Depending on the design, allowing vertically polarized radiation may result in worse or better VSWR.

Regarding the color, many straight people wear it over here (especially in summer days), so you can't judge on color only....

Regarding the balun/transformer, you need a very good one with OCF dipoles as common mode voltage at feed point can be in the 300V range

with 100W input. just some pF stray capacitance in a transformer will
provoke feed line radiation.

Best regards,

Wim

If anything is to occur it would be at the toroid which the water is
flowing thru. In this case the
diamagnetic material is the prime mover with respect to toroidal
field.
What the feed line is doing is not mentioned and it could well be the
toroid windings alone is doing all the radiating

Watch the video again. If we can believe that the video has not been
manipulated then, the signals are not present until the water flows ...

I seen this done many moons ago with a thick quartz tube(s) and a column
of mercury, mercury height varied to tune ... I'll bet the "mercury"
antenna is/was immensely more efficient ... the magnetic coupling would
be a great aid in NOT having to tune the match constantly ...

Regards,
JS

An HF antenna would need to put up a water stream "about 60 feet."

Hmmm, about 3kPa for each foot of water or about 200kPa. At Walmart,
for $320 you can buy a pump with a 2HP motor to do the job:
230V @ 11.2A

2.5KW to erect the antenna for a 100W HF rig. If you stacked 50 HF
rigs (end to end for more length), you would have both the same size
antenna, plus ALL of the 2.5KW of power going to RF and not water.

Very interesting indeed.

Wind would seem to be a weak point. The top of the conductive stream would dissipate at different heights depending on the wind velocity, so a gusty wind would be constantly altering the effective antenna length.

Part of the speal given talked about the scarecity of real estate for
the many antennas on ships! Why don't they use non frequency dependent
antennas so antennas can be shared, especially when in combat? And
what do submarines use for antennas
when in the stealth mode?

On 7 MHz a dipole constructed of salt water: Er = 81,
conductivity 5 S/m, and 0.5" diameter has a free
space efficiency of 0.08%. i.e. with 100 W input
the total radiated power = 80 mW.

Antennas which pop up out of the deck plating would be something. That idiot has just developed a very expensive toy ... and a very poor one at that.

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team. We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |
rec.radio.amateur.moderated |
rec.radio.amateur.space |

We are willing to provide any technical support necessary to get this
article updated and automatically posted again at a regular interval.
This would include establishing contact with the original maintainer for
any necessary permissions. We would prefer to seek a new, dedicated
maintainer at this time, rather than start auto-posting the original
article ourselves.

For more information about our newsgroup, see:
```

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to
rec-radio-info-request@panix.com.

In 1905 Einstein wrote: "Examples of this sort, together with the
unsuccessful attempts to discover any motion of the earth relatively to the
``light medium,'' suggest that the phenomena of electrodynamics as well as
of mechanics possess no properties corresponding to the idea of absolute
rest."

In "1925 - the Michelson-Gale-Pearson experiment produces a positive result"
(motion of the earth relatively to the ``light medium,'')

As you see after 1925 all predictions of SR and EM are the tales used in
schools to teach the math.

Takes a lot more HP to make a free flowing fountain that high.
Jet d'Eau in Geneva is 500 liter/sec with 2 500kW pumps (of course it is
140 meters tall)..(And yes, it is very impressive from a distance..)

The Buckingham fountain in Chicago is shorter (ca 50 meters) and has
much lower power pumps: 75,190 and 250 HP

> 2.5KW to erect the antenna for a 100W HF rig. If you stacked 50 HF

You can recover the energy in the water coming back down. If you have a
tube, you can either just feed the conductive fluid up the tube and fill
it (a sort of liquid SteppIR vertical), or, for fixed height, you could
have a recirculation.

This isn't particularly new or novel, by the way. The idea has been
around for decades (I think I saw some papers from the 60s analyzing
it). What's new is that the surrounding technology might have changed,
and what was impractical back then might be more practical now.

60 feet is not in the league of 140 meters or the shorter 50 meters.

However, to other comments, keeping it a column of water instead of
spray would certainly add to the pump load.

>You can recover the energy in the water coming back down.

Something like Hero's fountain? The proportions of this is growing by
leaps and bounds.

Which argues why not fill the tube with a tape measure instead?

The surrounding technology, literally, is the ferrite ring enclosing
the column. In 1960's dollars, cheaper perhaps but nothing newer. And
cheaper is relative - not particularly affordable.

That looked so bad I had to run an analysis to see for myself. Sure enough, it's that bad. And even with a 0.25 inch diameter column at 146 MHz, the efficiency is only on the order of 1%. A foot and a half of wire vs. a pump, power source, and ferrite transformer? No contest.

no, its positive result was the acceleration caused by the rotation of
the earth, as in the michelson-morley experiment they detected no
motion with respect to a fix or any other aether... otherwise the
result would have had a predictable variation due to time of day or
year, which was not detected.

On the surface, that statement simply sounds insane. It is always noon
on some portion of the planet and it is always summer somewhere ...

Naahhh.. everyone knows they drag an insulated wire, which is why NEC was updated some years ago to handle insulated wires in a conductive medium.

Now.. when their periscope is up, indeed, there's a lot of special stuff that goes into shared apertures. Look to the work of Jaumann in WWII..

And with sharing apertures.. it's not so much non-frequency dependent radiators that is the problem, it's isolation between the Tx and Rx. Multimegawatt pulses from your radar tend to raise cain with your sensitive receiver, even if your diplexer does have 100dB isolation.

Finally, it is challenging to make something that can efficiently radiate at a frequency while not reflecting that same frequency (i.e. re-radiating). Brings a whole new meaning to "match at the feedpoint" when your RCS has to be a tiny, tiny fraction of the physical size. (for reference, the RCS of a resonant dipole with shorted feed is about 0.2 lambda^2)

As it happens I bought a nuclear submarine radio transmitter with only
a few hours on it. It is a tube version so I assume the reason that it
saw so little service was when they determined solid state was not an

issue. Just for kicks today I put together 3 rolls of 50 conductor tape in series without unrolling them so the assembly was about 12 inches tall and 8 inches dia where as the antenna on the tower is about the size of a bow and arrow target and good for all bands without being frequency sensitive. Now the quick and dirty one was really 50 wires in parallel placed in series with end fed on two outside wires. Now it was only good down to and including 20 metres while sitting on the table next to the radio in a very cluttered shack with lots of equipment and on top of that it had no shield so you can't hang your hat on those results because of proximetry effect and other short cuts taken and yet the non frequency side of it is fully evident. So for a submarine or a ship in combat the long wire would leave an observable trace even when below the surface as the long wire will rise.
Same goes for ships that have radiators in the double or triple figures where when damaged control can be transfered to other non frequency sensitive antennas. I served in the Army so I have little knoweledge as to what goes on in the Navy and thus the question posed. Certainly such a antenna would be a lot more stealth like than the water jet stream proposed on U tube or even a long wire leaving a trail on the surface for aircraft to zero upon.
Regards
Art

John, all non frequency dependent radiators have to be shielded as it
plays havoc with the cancellation of reactance. But even with the
quick lash up I made where I broke all the rules and even changed to
"stacked pancakes" instead of coils inside coils it still would be ok
for directional use in a loft for some of the bands. Either way the
lash up did not totally destroy its attributes. I suppose it would be
more impressive if I shielded it plus a reflector and put it on the
tower but that was not the point I was trying to make which is the
persistance in keeping non frequency dependentcy
while maintaining a small volume. I modeled a ten turn coil inside
another ten turn coil where both were joined together as a closed
circuit and a overall diameter of 8 to 9 inches sitting on a perfect
ground ala reflector When an antenna is not frequency dependent there
is no skin depth resistance because of the Meissner effect so more
current is applied to generating radiation. This conforming to
Maxwell's law by not indulging in generating magnetic fields. Note
Maxwell never added units of Tesla in his equation so why should you?
By the way that model showed gain inbetween 20 and 30 db because of
current bypassing the innards of the radiator and traveling on the
surface.
So the old timers were correct in saying more wire is better....as
long as you decrease the resistance
created by adding wire!!!!!! That way you have
I sq R instead of I sq R + r which is efficiency in radiation to the
maximum.by removing unnecessary losses. Simple concept eh?
Regards
Art

the earth, as in the michelson-morley experiment they detected no
motion with respect to a fix

You assume that the ether is fix. The same did Maxwell. But Maxwell did it
before MMX.
You should know (after MMX and MGX) that the ether is not fix. It rotates
with the Sun but not rotate with the Earth (it was predicted by Stokes in
1845).

>or any other aether...

They "detected no motion" with respect to Stokes ether.

> otherwise the result would have had a predictable variation due to time of
> day or
year, which was not detected.

The results of MMX and MGX prove the Stokes ether.

Let's fix the wind problem and shorten the antenna!
Have the water spray up into a receiving vessel the distributes the water
into
5 or 6 radial tubes that make up a capacitive hat. :-)

While we're at it, let's spray out some radials for a counterpoise!

Hey, if we can catch all the water and recirculate it, then we can
add material to increase the conductivity of the water.
ok,ok I'll stop.
MikeK

Let's just fill a tube with water and provide sufficient heat-sinking to
keep the water at an acceptable temperature. Obviously, the idiot with
the sump pump and walkie-talkie realized the power of the publics'
fondness for toys ...

why don't you just go back to Opticks, thats only about 100 years
older than the almost 200 year old Stokes aether... you are still
going backwards dragging up old disproved theories.

It's a sad comment on the state of this newsgroup that an objective statement of what are believed to be facts is taken as "throwing [the engineer] into the lions' den". It's not my intent at all to impugn the engineer. Surely he's aware of the efficiency of the "antennas" he's creating, so either my (and Frank's) calculations are grossly incorrect or SPAWAR thinks there's a market for such inefficient antennas. It would be educational to know which of these is the case. It was interesting that there was no mention in the video of very low efficiency, but I guess that's to be expected for a promotional piece produced by a marketing department looking for investors.

The point I caught, and apparently was not modeled, was the discussion of antenna height for any particular band. Albeit, such mention was fleeting, but it sounded suspiciously like half wave, not quarter wave dimensions.

Aside from that speculation, power specs for military usage are appropriate for theater operations, not global communications. When I taught UHF/VHF in the Navy, 10% efficiency was considered perfectly acceptable as point-to-point communications was the only expectation and that was rarely as much as 20 miles at best. Experience teaches that even that only takes 100s of milliwatts.

That's still an order of magnitude better than what this antenna seems able to do at VHF, although the demonstration clearly showed it to be adequate for working a local repeater with an HT.

But what about HF, which the video clearly mentions? Is a fraction of a percent efficiency adequate for typical communication needs? I know that some military HF use is NVIS, for which a vertical antenna is poorly suited to begin with, so that probably wouldn't be an application. Are milliwatts of radiated HF used and useful for theater communications?

Hawking radiation seems to be caused by the quantum soup complementary
virtual particles that wink in and out of existence in space. Instead
of being spontaneously annihilated, one of the complementary virtual
particles falls into the black hole and one escapes thus becoming a
real particle.

Hello boys, good day for you

Is it Carolina Windom a balanced load to justify the name "balun"? We could think in a device to transform Z and another device to block feed line current. What do you think about it?

Miguel

Yes, I see your point, and agree. I have never ran a windom or experimented with it, so obviously, others are much more knowledgeable with them. However, logic tells me they would be one easily justifiable situation to use a voltage balun ... the CM currents being looked at separately ... the balun must have a definite and pronounced effect on pattern with this particular antenna.

Now I'll listen.

People trying to resurrect old and not very plausible theories by equating quantum soup to "aether", or even phlogiston is a great way to dismiss their ideas. Maybe the flat earthers are right too - we just haven't found the right proof yet.

It's all the same, ether (aether), but like all things which some find disgusting, some attempt to play word games, like renaming a rose ...

Another example: homosexual = gay

Stupid if you ask me ...

The last line is telling. If you choose nature over God, you will lose.
A lot of people choose religion over science, and apparently always
will. To the point where I have heard just this year both that God
placed fossils in the earth and that Satan placed fossils within the
earth. The former as a test of faith, and the latter as temptation.
Though of course why God would put something in as a test of faith by
the positive outcome being a rejection of the evidence seems a little
strange.

So if people can dismiss actual physical evidence, it is no surprise
that they will reject evidence of a more aetheral nature.

It's their right, always important to remember is that we are all going
to hell in someone's religion.

Before beginning a discussion about what constitutes a balanced load and what doesn't, how about answering these questions?

1. What is "balance"?
2. What defines a "balanced" feedline?
3. What are the properties of a "balanced" load?
4. How can you tell when a line, load, or transmitter is "balanced"?
5. What's the big deal about being "balanced", anyway?

And finally,

How does a balun achieve "balance"?

Tell 'em one thing "balance" means is if you have a funky antenna depending on feedline currents/radiation/etc. you don't start chucking a bunch of stuff in the feedline without expecting patterns to change ...

ah, you think because they mention the gps system using the
corrections that were detected by the mgx experiment that there must
be an aether... but you are wrong, the gps system uses the
acceleration corrections predicted by special relativity that were
verified by the mgx experiment... there is no aether involved, it is
the acceleration caused by the rotating earth that causes the effect.
but of course you won't believe that and will insist that it is
because of aether dragging, but that would cause many other effects
that are NOT observed... in order for a theory to be right it must do
2 things, it must predict something that can be observed, and it must
not fail ANY test that would disprove it. all the aether theories
have failed at least one test over the years and are therefore
incorrect.

What does the rotating earth accelerate? Light, RF? The speed of light is fixed within its' media, the ether, the only way to accelerate EM is to accelerate the ether itself ...

The exact same arguments you state can be used as an argument for the ether as well as SR ...

Hello Roy

Why? that way we can end up having to define all words we use :>). I
learnt a two terminal balanced circuit basically have the same
impedance respect to ground in its terminals, if Windom Carolina not
have it, well... we have missed the "bal" part of the equation :>)

I recognize the other items are interesting to analize too but in
diferent sense that the proper use of the term "balun" towards I
pointed my little observation.

Years ago I have read your very good article "Baluns: What They Do
And How They Do lt" (until today I keep it safe in my computer for
reference) and I believe I understand where you point to with the
other good questions.

For John: Dear friend I could not translate well your post, may you
repeat in a little more Tarzan english for me?

Miguel

Suppose you connect a transmission line to a perfectly symmetrical, horizontal antenna. The antenna and feedline would be a "balanced circuit" by your definition, since the two conductors of the transmission line have equal impedances to ground. But the transmission line will radiate.

Now connect one conductor of the transmission line to the center of your rig's coaxial connector, and the other conductor to the rig's chassis. (This is Fig. 2 of the article you mention, which by the way is available at http://eznec.com/Amateur/Articles/Baluns.pdf.) Is it still a "balanced circuit"? Why or why not?

Or suppose you take two signal generators which are perfectly coherent (i.e., phase locked to run at exactly the same frequency) and exactly in phase with each other. Each has a 50 ohm output impedance and each produces exactly 1 volt RMS of RF when open circuited. Connect one of these to each of the terminals of the feedline instead of connecting the feedline to your transmitter.

Now,
-- The impedances to ground looking toward the antenna from the feedline are the same for the two feedline terminals.
-- The impedances looking back toward the generators from the feedline are the the same for the two feedline terminals.
-- The two feedline conductors have equal voltages and currents.
-- The circuit is surely balanced by your definition.

Yet the feedline will radiate. Change the generator phasing any other angle except 180 degrees, and the feedline will radiate. Only when the two generators are exactly out of phase will the line cease radiating. I call that condition "balance" for the reasons explained in the article, but it's quite different from your definition.

If we're to use your definition of "balance", we have to conclude that balanced transmission lines radiate some times and some times they don't. If the system is already "balanced" when the generators are zero or, say, 90 degrees out of phase, would a balun do anything if connected between the generators and transmission line?

Stokes ether not fail ANY test.

> all the aether theories
have failed at least one test over the years and are therefore
incorrect.

The only one ether theory have failed. The solid dielectric ether. That described by Heaviside:
http://en.wikisource.org/wiki/Electromagnetic_effects_of_a_moving_charge

" It will be understood that I preach the gospel according to my interpretation of Maxwell, and that any modification his theory of the dielectric may receive may involve a fresh kind of propagation at present not in question."

"All disturbances being propagated through the dielectric ether at the speed of light,"

Now is like Cecil wrote: "Assuming the aether is the same thing as the quantum soup, EM wave
propagation would not be possible without it. "

The next name is the "Interstllar Medium". The each soup must rotate with the Sun because it is the Sun's product.

The soup is not the dilectric. It is plasma and as it is a conductor like metals. Your radio waves propagate in the same manner in the metals and the soup. They also propagate in a dilectrics as the displacement current.

But of course you won't believe that and will insist that it is because of SR.

Even if you remove the misc quantum particles empty space isnt
nothing. The problem most people have with their concept of the
universe is thinking of totally empty space as nothing. Space even
completely void of energy and various subatomic particles is still
something. We know that something can be altered so if you want to
call it Aether go ahead, a rose by any other name.....The present
title is usually space/time.

You touched on one major problem there, which throws most people off and keeps them from being able to realize there is an ether, time. There is no such thing as time which you can put in a bottle. There are no time wells, there is no time flow, time is an imaginary concept.

Time is simply movement and distance conceptualized into a singular "thing." No one has ever experienced time, they experience movement and distance. No device has ever been created which can measure time or, even, detect time. Our very best and most technical clock only measures movement and distance, or loss of mass (movement of electrons away from the main mass.)

If you have your mind locked into the space where it still conceptualizes time as a real thing, it is going to be difficult to make the jump in thinking to be able to conceptualize the ether. The ether is what allows a concept like time to look real, a medium for things to move through and required for anything we are seeing happening to occur in.

A coil of wire is a poor radiator for the same reason balanced
transmission lines for most all practical purposes do not radiate.

Nope, it's not. Nothing that is completely devoid of energy/matter is absolute nothing, i.e. zero volume and outside of the boundaries of our universe, i.e. our space is a property of matter/energy. That absolute nothing is what allows parallel universes to exist with zero communications between them. The space contained by our universe is a bubble caused by matter/energy. Outside that bubble is absolute nothing.

I don't think so. We have nothing which can "touch" either, no "bottle" we can hold some portion of it in ... and a soap bubble can't exist in a vacuum ... I doubt if an either bubble can exist in "nothing." At the very least, there would be yet another undiscovered media which supports ether in the same manner with our ether supports our matter, and does interact with ether ... but, that is only using logic.

I seen some news on the hadron collider ... they are moving up the time frame when a lot of their predictions, on new particles, should be found/proven ... I forgot to bookmark it. If I find it in the future I will post it here ...

no, sr is not necessary for propagation. and a dielectric is not
necessary for displacement current. nor is plasma necessary. you are
still very selective in your reading, a simple search shows that
stokes as well as all the other aether theories have been disproved
for nearly 100 years now.

you obviously don't know the difference between speed and velocity and
how you can accelerate something without changing its speed. in any
case, if there were any kind of aether dragging or acceleration it
would cause shock or bow waves of compression in the aether at some
point that could be detected by variations in the speed of light in
different directions. this applies for earth dragging aether, or mr.
b's sun dragged aether.

> ... I doubt if an either bubble can exist in "nothing" ...

That's exactly what I was trying to say. The quantum soup that we call "empty space" within our bounded universe is not empty. Space within our universe can never be absolutely empty and always contains at least dark energy which comprises ~70% of our universe. It is sometimes called zero-point energy, surrounds us, and allows us to exist. From Wikipedia: "Zero-point energy is sometimes used as a synonym for the vacuum energy, an amount of energy associated with the vacuum of empty space. When the term is used in this way, sometimes it is referred to as the quantum vacuum zero point energy." Absolute-nothing, i.e. less than zero-point energy, is the complete absence of any type of matter and energy. Space cannot exist within absolute-nothing which is what makes parallel universes possible. Instead of asserting that space contains dark (zero-point) energy, it would be more correct to to assert that space is the *result* of the pressure of dark (zero-point) energy, i.e. the quantum vacuum that we call "empty space" is *caused* by the existence of zero point energy left over from the big bang - also responsible for the present expansion of the universe.

has anyone linked zpe or 'quantum soup' or dark energy to
electromagnetic waves in a way that preserves the constancy of the
speed of light in all reference frames? or related those phenomena to
epsilon or mu of free space?

You will go to any complexity, any obfuscation, any devious explanations of enormous proportions ... it is easy to recognise befuddle confusion, it looks just like all that BS.

When you get to the real explanation, it is simple, you will know its' truth by the beauty of its' logic. The creator didn't construct all the other parts of the universe thus, but when he got to the ether decided to make it enormously complex ... you should be ashamed, your IQ is showing ... what is the temperature of this room?

Got cha'. Close enough, I agree, we do agree ... we wear the same hat.
It is actually platinum foil, those fools over there think it is
tinfoil! ROFLOL

However, only logic and reason dictates the above, which you correctly
posted. If you believe in magic, bullets shoot from our antenna(s)
across an empty void ... and sugar plums dance on the heads of pins.

Yes, well gather all your self-important BS around you, along with those you can impress with your cr*p ... and have at it ... I can safely dismiss you as a malcontent and chit-stirrer.

Frankly, I will give you this, the benefit of the doubt: I am not sure you are doing it intentionally, you could actually believe it. None-the-less, it is still what it is ...

of course i am doing it intentionally, stirring up art and mr.b is
just pure amusement. their science is pure junk, mr.b has been going
backwards in time for a while now dragging up ancient history that has
been well debunked. art just makes up technobabble based on whatever
he thinks he sees jumping off his antenna that day.

You build your premises on card board with rube goldberg logic and mechanics ... Einstein had to renege and accept the gravitational ether, without it his relativity falls apart ... you waste my time and are given to grandiose delusions ... you can't even recognize the impossibility of your own argument(s.) But, you want me to take it seriously ... I find that, a lot, but around people I usually choose to avoid. Some think homosexual marriage is logical ... I have seen it all.

Yeah, you are like richard clark, you base beliefs and claim facts depending on who states them, and proudly so, it is not the context of the statement, it is who said it, the above is an excellent example, in your own words. A million men can be wrong, just as easily as one ... especially using the your method, above ... an echo chamber is not a place to seek truth.

You probably think 9/11 wasn't an inside job too ...:
http://www.prnewswire.com/news-releases/architects--engineers-for-911-truth-announces-hard-evidence-of-explosive-demolition-of-world-trade-center-high-rises-on-911-102519299.html

There are your experts, engineers architects ...

The speed of light is measured in length/time, e.g. 186,000 miles/
second. Given that relativity affects both length and time in
different ways, wouldn't you say that the choice of the speed of light
as a universal constant was somewhat arbitrary? Why should a universal
constant involve 0.416667% of one rotation of the earth? What did the
universe use for a second-of-time reference during the 8? billion
years before the earth was formed and started dictating the length of
a second? IMO, the universal speed-of-light constant is just an
arbitrary reference point that had to be cast in stone before the math
would work.

If we stretched a physical cable between our galaxy and a receding
galaxy and found that the cable didn't break even though the galaxies
were receding, what could we conclude? I have concluded that the red
shift is not because the galaxies are receding faster and faster but
because the velocity of recession is actually slowing due to gravity.
What we perceive as recession contains relativity effects due to
decreasing velocity which causes space to expand and seconds to become
shorter. 186,000 miles gets longer and one second get shorter The
resulting length/time calculation is a double whammy red-shift error,
IMO. The universal speed-of-light constant only applies to a lone
observer capable of immense rationalization.

You do not know that the reference frames are dragged:

""Frame Dragging
One of the strangest predictions of the general theory of relativity
concerning black holes is called frame dragging. For a rotating black hole,
the theory predicts that space and time itself can be dragged by the
rotating black hole. The adjacent figure shows an artist's conception of
this idea (J. Bergeron, Sky & Telescope: get permission; Ref). Some recent
data has been interpreted as supporting evidence for frame dragging around a
black hole (Ref). "
From: http://csep10.phys.utk.edu/astr162/lect/blackhole/blackhole.html

If you do not like the Sun's ether drag you can use the Sun's reference
frame drag. Which one do you prefer.

> or related those phenomena to epsilon or mu of free space?

The space is not a dielectric. Electric waves travel in metal transmissing
lines where no epsilon or mu.

Having dealt with water streams for a while, I wonder how the stream
is measured, because all streams break up into droplets at some point
well before they appear to do so.

John
Look at his last 100 posts and check to see if you find one of them
informative and then question why you even respond to him? I mean it.
He sends nothing but trash all the time. Anybody can say "babbling
nonsense" but not anybody can explain
babbling nonsense unless he himself is well practiced in the art!

You are absolutely correct. Would be interesting to have real time monitoring of the match, field strength in relation to a standard 1/4 wave and real power delivered to the water stream. I am thinking this is the dummies, dummy load. Or, the dummy load of the century ... could sure use a 5KW ferrite core like he has, just sink the signal into a "barrel of saltwater dummy load" ... would be nice to be have this dis-proven and start discussing why.

Who knows, when the stream goes "live" perhaps the feedline "lights up" as a radiator. As someone already pointed out, the repeater makes one highly suspicious. I mean, is he line of sight from the repeater? How far is he from the repeater? Why didn't he just choose direct contact? Etc., etc. He certainly could have supplied us with better.

I just might write him and ask him for a new youtube video and different test parameters.

Regards,
JS

To state it a bit more clearly - who can make a living based upon their
stand on what's real? That always separates the wheat from the chaff.

Mr B, Art, Doctor Smith, how'r you all doin' in the antenna consulting
and/or sales and design business?

I expect very well considering you know more than the rest of group that
hangs out here.

Please insert ill considered response 6 lines below.

Hello Roy, good day.

I prefer not use "my" definition or "your" definition words because in this case -at least- I am not the "definer", I only learnt that definition. Anyway, a definition it is not neccesarily a "true", you can define a gnome or a dragon, both inexistent or "untrue" critters (I am not absolutely sure about its "inexistence", hi hi). A

definition may be simply the conventional meaning of a term, true or false it is not applicable to it, different logical thing it is a "proposition".

Well, long time ago I learnt a definition of balanced circuit, that definition not mention simmetrical driving to the circuit, only impedance respect to ground. Citation =>

Balanced circuits: "The pad in fig 133 it is a balanced circuit (or balanced pad) because there is the same impedance in each line wire. A properly constructed open wire line or toll cable is also a balanced circuit."

(From "Fundamentals of telephony", by Arthur Lemuel Albert, McGraw Hill, 1943, page 265).

I know Wikipedia it is not authoritative but in "Balanced Line" says:

"In telecommunications and professional audio, a balanced line or balanced signal pair is a transmission line consisting of two conductors of the same type, each of which have equal impedances along their lengths and equal impedances to ground and to other circuits. [1]"

Searchiing the Web for definitions I found an interesting article in that item with similar concepts
http://www.multimediamanufacturer.com/articles/whitlock407.pdf
Can you acces to an IEEE definition? I could not.

I believe original definition perhaps was related only to noise pick up in lines, I understand your point and not oppose to it, it is a good point, perhaps we have to say "an all (o totally) balanced SYSTEM" when we want to refer to both (signal and impedance) simmetries, to eliminate ambiguities.
.....
Although this is a more important issue, I insist in my original point, is it "licit" to call "balun" a device connected to two unbalanced circuits (line and antenna)?, Is it Carolina windom a balanced antenna?
Here most of hams tend to call balun any toroidal transformer, with TL or traditional windings connected to any circuit! :>)

What you say? Thank for your interest and answers. Best regards to you and all friends.

Actually, balun = "balanced-to-unbalanced", and unun =
"unbalanced-to-unbalanced." I believe that is correct.

And, I am in agreement, I see isolation RF transformers, RF
auto-transformers and transmission-line-transformers and UNUNs' all
grouped together under "balun." It would be nice to have standardized
terminology and everyone is encouraged to use it ...

Other than that, the rest of your post is sure to fire debate, assuming
that everyone even recognizes the above ...

Hello all

OK, this probabily is near a joke or hoax, but what about liquid/ionic/
dielectric in general? I have a pair of interesting links about it =>

http://ieeexplore.ieee.org/xpl/freeabs_all.jsp?arnumber=1461138
http://xa.yimg.com/kq/groups/15085895/1136140553/name/Trees_Antennas_IEEE.pdf

Time ago I had some doubts about the mobility of ions in a liquid to
radiate and calculate how much an electron actually moves when the
antenna is radiating to use as a starting point.
The numbers (if I do not make mistakes) showed me to a current density
in the order of 5 A/mm^2, free electrons can take a trip of just one
three thousandth mm of copper ion radius, surprising result!, really I
did not expect such a small value ..., It showed me that electrons in
antenna barely vibrate around their resting place when radiates (I
made calculations for a irradiant at 80 m).
This favored hypothesis of liquid antenna possibilities because would
suffice for the ions (charges) of the liquid vibrate slightly around
their points of rest to act as radiators (I do not to solve issues
related + ion mass to best "close" my questions).

We know sea water an earth EM wave reflections really are
reirradiation of EM energy, then, ionic antennas there are real
things, are there? However I haven not study the efficience of this
process.

What do you think about it?

Best regards

As you get older, you are slow to call anything "impossible." Many, many things which were accepted as "impossible" as a teenager, are now done daily as I am an old adult ...

However, unless there are some really unique methods discovered/found/invented/etc. for the manipulation of physics involving seawater and RF, a "seawater antenna" still remains in the realm of "impossible", for now ... at least for me ... and by that, I mean taking sanity into consideration ...

Hi Miguel,

This reference is much better than your first citation - it mentions
what the common (earth, ground, other circuits) is, which is necessary
for symmetry AND balance. Your first citation merely described a
loop. A loop is symmetrical within its own self, but that doesn't
make it balanced.

>Searchiing the Web for definitions I found an interesting article in
>that item with similar concepts
>http://www.multimediamanufacturer.com/articles/whitlock407.pdf

This link gives a good introduction to common mode which is central to
the problems of balance and symmetry.

>Can you acces to an IEEE definition? I could not.

No point in that.

>I believe original definition perhaps was related only to noise pick
>up in lines, I understand your point and not oppose to it, it is a
>good point, perhaps we have to say "an all (o totally) balanced

No, that is not complete.

>......
>Although this is a more important issue, I insist in my original
>point, is it "licit" to call "balun" a device connected to two

The word properly formed is BalUn - balance/unbalanced transformer.
Similarly you have a BalBal, and an UnUn so that other topologies are
properly termed.

>Is it Carolina windom a
>balanced antenna?

No.

>Here most of hams tend to call balun any toroidal transformer, with TL
>or traditional windings connected to any circuit! :>)

The term was not coined through a democratic vote - they are wrong.

Hi Miguel,

Let's see, half the power lost to the antenna:
"A simple monopole antenna was constructed and its reflected
impedance and radiation efficiency measured for salt solutions
of 2 conductivities and 2 monopole diameters. Two antennas
were constructed, 25 mm and 50 mm in diameter, with salt solution
at 35 ppt and 70 ppt. The resonant frequency was found to
be inversely proportional to salt solution column height,
with bandwidths of ?1 GHz (-10 dB S11 points) at 1.3 GHz."

A quarterwave monopole @1.3GHz would be 5.8cM tall and up to 5cM in
diameter? A mylar balloon filled with air (not water) wouldn't lose
half the power applied. Voila! Wide band, 3dB gain, lighter, and can
be made into any shape.

>http://xa.yimg.com/kq/groups/15085895/1136140553/name/Trees_Antennas_IEEE.pdf

This has been a topic here going back at least 15 years.

Consider a dielectric lens antenna. How much mobility there?

>We know sea water an earth EM wave reflections really are
>reirradiation of EM energy,

This reflection is a function of a severe mismatch between two poor
conductors. You don't need sea water to achieve the same thing.

Hello dear Richard, how are you? I hope very well with yours:

Mylar conductive ballon replacement it is not a valid refutation for the hipotesis analized, that antenna was only a "test antenna", any liquid antenna can be replaced by a metalic antenna...! what prove that?

I was not be here fifty year ago :>) (I suppose "ether" also must have been treated in this newsgropup a hundred years ago :>D) what you think about it (trees) at that time?

I do not know lens dielectric antennas, I learnt radiation it due accelerating charges, electrons are charges, free ions also, non free dielectric charges (E field induced dipoles) too; alternating electric field applied to them produce movement on them, then acceleration, then => radiation. Am I wrong? (yes I know, loss too sometimes).

You say: "This reflection is a function of a severe mismatch between two poor
conductors. You don't need sea water to achieve the same thing"

What "two" conductors? you know air not work as a "conductor" in this analitic environment, it would the same it there were empty vacuum, reflecting medium properties are responsibles for earth reflections.

"Mismatch" it is another magic word, improper of you indeed my friend!, not an explanation :>)
Classic EM radiation (or the same "re-irradiation") it sometimes explained due accelarating charges, and YES, I agree with you, certainly "you do not need sea water to achieve the same thing", you can do it with any other vibrating charge, sea water charges it is only one possibility, conductors, soil substances are other familiar things capable to do it.
We know waves are reflected to ionosphere by those mediums, we can explain that reflections with incident electromagnetic fields and earth surface induced currents; however, "current" not implies here free electrons traveling miles inside a conductor, we have a "current" with any little induced movement on a charge and if this movemente is not constant we have acceleration then => EM radiation, what other classical process could explain the EM earth reflection? I do not know.

However I am not supporting practical liquid antennas here, I have not made the experience and I have not theoretical enough knowledge neither to prove or refute the hipotesis without much more working, I only have some pointers to think over about it.

Hi friends

Well... I believe we mostly agree for our internal use, but, there are a authoritative formal definition? because I do not found it, the only ones I found were about impedance balance, not signal implied, however it results strange to me because telegraph and phone lines crosstalks depend on current balance in wires too, then I think old engineers should be taken into account, my old RF and telephony books tends to not use balance word but "symmetry".

I haven not problem with your/our concept, but have we power enough to become "The Definitors"

Why "do not point in that" Richard you do not trust in IEEE guys? :>)

> could think in a device to transform Z and another device to block
> feed line current. What do you think about it?

Miguel,

Sometimes the language we use doesn't well describe the thing we are thinking about, and this is a case.

We could well apply a meaning to balanced, that either the currents are equal in magnitude but opposite in phase; or that the voltages wrt some sensible accessible reference are equal in magnitude but opposite in phase. One does not imply the other without constraining the load characteristic.

When we speak of unbalanced, we commonly think of a configuration where one side is 'grounded' and the other 'active'.

The problem is that many situations in antenna systems are not purely either, they are not balanced by one or other of the meanings above, and they are not unbalanced by the meaning above.

So, they need to be dealt with by the more general method of considering that there are non-zero common mode and differential voltages and currents.

It would be most unlikely that a Carolina Windown would be balanced, or near to it, by any defintion. The antenna is born out of a quest to sell the disadvantage of Windom feedline radiation as a positive feature.

The way I like to explain a balun is that it *facilitates* connection of a not-balanced device to a balanced device. A practical balun does not, of itself, eliminate (meaning make zero) common mode current or common mode voltage... yet we commonly use absolute words to describe its action.

To a certain extent, that is saying that they are not ideal or perfect devices. Some of the rules we hams have made for baluns pretty much assure mediocre performance. Like for example what I refer to as Rule 500, that the minimum choking impedance of a current balun is ten times the differential characteristic impedance (commonly 50, hence Rule 500).

I know English is not your first language, but be wary of applying the meaning of words absolutely.

>that?

Hi Miguel,

What does it prove? What does water prove? That it is a poor
replacement? Yes.

>I do not know lens dielectric antennas, I learnt radiation it due
>accelerating charges,

That repeated epithet is rather too simple. An electron is always
accelerating. A circular orbit guarantees that.

>electrons are charges, free ions also, non free
>dielectric charges (E field induced dipoles) too; alternating electric
>field applied to them produce movement on them, then acceleration,
>then => radiation. Am I wrong? (yes I know, loss too sometimes).

Does swinging a battery around produce radiation?

>You say: "This reflection is a function of a severe mismatch between
>two poor
>conductors. You don't need sea water to achieve the same thing"
>
>What "two" conductors?

POOR conductors.

>you know air not work as a "conductor" in this
>analitic environment,

Right, it is a very poor conductor (and, yet, we still see lightning
conducting through it on a summer evening - all a matter of degree).

>it would the same it there were empty vacuum,
>reflecting medium properties are responsibles for earth reflections.

I suppose so.

>"Mismatch" it is another magic word, improper of you indeed my
>friend!, not an explanation :>)

Magic happens.

>Classic EM radiation (or the same "re-irradiation") it sometimes
>explained due accelarating charges, and YES, I agree with you,
>certainly "you do not need sea water to achieve the same thing", you
>can do it with any other vibrating charge, sea water charges it is
>only one possibility, conductors, soil substances are other familiar
>things capable to do it.

So then, classic EM radiation is pretty common, and has lost its
magic.

>We know waves are reflected to ionosphere by those mediums, we can

Hello Owen, it is a pleasure to meet you again.

Oh, yes, of course here we use our words with freedom too. I confess I call "baluncitos" (little baluns) the little toroid transformers, specially binocular ones, but in this newsgroup a lot of good people is very strict with wording and precision of terms :>) then I thought it was no exaggeration from me ask whether it is correct use the term "balun" when both sides are "un", hi hi.

However certainly many times in our hobby words are a true trap for novice (and not so novices), then, why not to call things with more proper name?, if a balun do not "baluning", well... call them "seudo-balun" or another similar pointer to true behaviour (as our known "pseudo-Brewster angle"). There is not a languages translation issue here Owen, you and we, in english and spanish, missuse the same words and concepts, the "thing" it is "globalized".
I am far of being a purist of the tongues, but you know, we hams have misleading words, a majority of you are true experts in RF and it is difficult you can become confussed. Anyway, is not something to worry so much either, the mine It was a casual comment, blame to Roy by take us to the hard theory :D :D

Greetings

Miguel

The answer to your question about a Carolina Windom is yes. The answer is also no. It all depends on what you mean by "balanced". You shouldn't have any trouble finding an authoritative source to justify either answer.

I have no interest in establishing or arguing about an "official" definition of "balanced". What I'm trying to do is force people to define what they mean when they start talking about whether a balun achieves "balance" in some particular system, or whether some antenna is more or less "balanced" than another. As I hope you've seen, the conclusions can be very different depending on what you're trying to achieve by establishing "balance". In my article I pointed out that achieving "balance" of feedline conductor voltages relative to the Earth or some chosen "ground" point can often *cause* feedline currents to be other than equal and opposite, and therefore make the feedline radiate.

Until you clearly define exactly what you mean by "balance", discussions about it are useless because it means so many different things.

I'm far from a language purist -- my vocabulary and standards of diction were largely formed during my military service, which is why my vocabulary is so limited -- in popular company the majority of my literary repertoire is unacceptable and unavailable for use.

But I am big on communication, and really hate to waste my time arguing about senseless things, especially when people can't even rationally formulate what they're arguing about. (That's why I plonked Art, "John Smith", and a few selected others long ago.) Feel free to use words any way you want. But if you use them in an unconventional way (like Art uses "efficiency") or use words with multiple different common meanings (like "balance"), then you won't be communicating but just blowing wind unless you take the trouble to say exactly what you mean. Most people resist doing that because they're not too sure themselves just what they're talking about.

The postings here show that just blowing wind is a very popular pastime for a lot of folks. But it isn't my cup of tea.

Perhaps the term 'common mode choke' works?

I did see a raging argument someone online (eham?) just recently where parties were arguing that a 4:1 Guanella current balun could be wound on a single toroid, it was the way Guanella intended it they said, but they argued that use of two ferrite sticks for such a device was wrong.

In fact, Guanella's article describes his 1:1 balun without any magnetic core material, and the 4:1 balun as a connected pair of 1:1 baluns with no (ie negligible) magnetic coupling. Yet I have seen commercial sites selling a Guanella 4:1 current balun on a single core, arguing that Sevick said it was ok in a certain context... a context that is unlikely to ever exist in an antenna system. But hey, Sevick is Mr Baluns, so they sell. That context relates to another dimension of the balanced / symmetric issue.

Back to the Carolina Windom, a common explanation holds that there is common mode current on the feedline between the dipole feedpoint and the 'isolator'. The notion that common mode current exists on one side of the isolator and not on the other is an interesting one, one better explained by advertising hyperbole than radiocommunications theory.

The first part, above, implies that no one has ever constructed such a balun(s), one on a single core, one on a dual core, used "balanced" resistances, to serve as loads, then unbalance the loads, and observe results. I have, when constructed properly, one can be constructed on a single core. Is the dual core better? Yes ... is it possible to run the single core balun in conditions where it will fail miserably?; Yes. Is it possible to run the dual core balun in conditions where it will fail miserably?; Yes.

As to the second part, I have found a properly constructed balun to be both, a choke and "impedance-transformer." Indeed, an excellent balun is optimized to take advantage of both phenomenon.

And, of course, I have found and believe a 160m to 10m balun/unun is stretching things, probably beyond what one should (but, hey, you can get by with it), two baluns, a high freq and a low freq are better to cover such a span ... however, you can carry that to an extreme and optimize core material/size and windings for each specific band ...

And, radio is an onion, each layer built on a preceding layer. At the core of all this is the EM transmission theory, and RF is both particles and waves ... obviously, both have great difficulty being true at the same time, so "waves of bullets" becomes the explanation ... obviously, great difficulty is going to be had in having cement solid theory in the outer layers of this onion. By the time you get to "balance" the errors are only magnified ... balance is like any balance in life ... you'll know it when you have it, and benefit from it.

Regards,
JS

I agree with you Roy in several items, when we try communicate with words and we not share the exact word meanings we end up inmersed in the Babel course. Moreover, we later build bigger ideas based in that misunderstood words, then it is not rare that at the end of the process we can not agree almost nothing.

But there is a problem, explain our concepts writing in a paper it it is not ease too, any dictionary it is circular referenced, verbal or written definitions use words, then such circularity it is inherente to written language in some point we will need to point to an object, event or phenomenom and say to our partner: you see "this is a house", "that is a river". That way we learn languages when we born, linguists call them "ostensive definitions".

Because that, I pointed -in early post- we could end up having to define all words we use. Here we call that process "socratic tests", because a teacher could ask and ask definitions recursively to the extent we were not able to explain even what is a mom.
Also, in some point we need support us in standard accepted definitions of terms with its limitations at risk of failing to have a common language, often authoritative definitions serve to this pupose even although they are incomplete.

I do not would say I hate to waste my time arguing about apparently senseless things because what to me may seems nonsense can be really important and I am not capable to see it, but I agree that comes a point where I tired and renounce (and there are much things that are really suspiciously foolish). However I recognize that drop the bone too early sometimes not conducive to resolving difficult issues, it is all a matter of "balancing" :>)

Thank you very much.

Miguel

PD: Nice examples of english meanings, when we tell: "ese es un hijo de su madre" we are not talking about kinship relationships :>)

Suppose I buy a roll of thin wires, install multiple hooks at the
corners of my rectangular room, then wrap the wires along the hooks,
then connect the 2 ends of the loops into my hi-fi.

Would that make a great AM antenna? Would it work?

How about, "I could care less." vs "I couldn't care less."?

From "The IEEE Dictionary": "balun - A network for the transformation from an unbalanced transmission line or system to a balanced line or system, or vice versa." They mention the transition from twisted pair to coax. "Unun" is not in "The IEEE Dictionary".

As you know, common-mode RF obeys the rules of the reflection model.
From an (ideal) physics standpoint, there is nothing technically wrong
with having zero common mode current between the isolator and the
source while having a common mode current maximum (loop) 1/4WL back
toward the antenna feedpoint from the isolator. (Assume an ideal
isolator with an infinite choking impedance.)

Consider the following example:

Source--------1/2WL coax1--------isolator-------1/2WL coax2----------
antenna feedpoint

The net common-mode current on each side of the (ideal lumped)
isolator must be equal to satisfy Kirchhoff. There is no technical
reason why the net standing-wave common-mode current could not be zero
on each side of the isolator where the isolator is causing a standing-
wave current node (minimum). 1/4WL back from the isolator toward the
source, there is no technical reason why the net standing-wave common-
mode current could not be zero. 1/4WL forward from the isolator toward
the antenna, there is no technical reason why the net standing-wave
common-mode current could not be at a high (maximum-loop) value. Since
it is theoretically possible, one should not dismiss it as
"advertising hyperbole" without having performed the measurements to
prove that particular statement applies to the Carolina Windom because
of poor isolator performance, not because it violates Kirchhoff's
laws.

Incidentally, this is the same conceptual error that some folks have
made when they reported measuring no phase shift in the current
through a large air-core 75m loading coil when installed on a standing-
wave antenna. Hint: Pure standing wave current has zero relative phase
shift so it obviously cannot be used to measure phase shift. EZNEC
confirms that fact.

Good mornig:

I agree with Cecil, Owen, I do not see nothing strange on have common mode current in one part of the line and not in the other, ideal choke it is an open circuit to RF currents.

In Carolina we have at least a pair of possibilities: employ a conventional transformer with pure magnetic coupling (shield betwen windings), then we get Z adaptation and no common mode feed line current or employ another more BW efficient Z transformer with less isolation to common mode current + a common mode choke.

Respect to balancing definitions, I would like to use here a universally agreed definition because we -hams- exchange conceptual and technical information with people of all the world who often study electronics in colleges and universities; seems reasonable to me use a common lenguage. In this newgropup (as others) there are much conceptual and meaning differences, cause that we can not autoreference internally controversial definitions/concepts. I am not a fan of Wikipedia, but its politics to ask for references it is valid and valuable.

>Time ago I had some doubts about the mobility of ions in a liquid to
radiate and calculate how much an electron actually moves when the
antenna is radiating to use as a starting point.
The numbers (if I do not make mistakes) showed me to a current density
in the order of 5 A/mm^2, free electrons can take a trip of just one
three thousandth mm of copper ion radius, surprising result!, really I
did not expect such a small value ..

In the lattice are the ducts. Not all electrons are in them.

>., It showed me that electrons in
antenna barely vibrate around their resting place when radiates (I
made calculations for a irradiant at 80 m).
This favored hypothesis of liquid antenna possibilities because would
suffice for the ions (charges) of the liquid vibrate slightly around
their points of rest to act as radiators (I do not to solve issues
related + ion mass to best "close" my questions).

Ions in copper vibrate with the acoustic frequencies.

>We know sea water an earth EM wave reflections really are
reirradiation of EM energy, then, ionic antennas there are real
things, are there?

At the higher frequencies the AC conductivity increases.
So there are more electrons.

>However I haven not study the efficience of this
process.

Consider that on the Earth is excess of electrons.

Message-ID: <W8ednXz2899Y_hPRnZ2dnUVZ_jOdnZ2d@giganews.com>
Source record: 7495

The difficulty with having common mode current on one side of an "isolator" or common mode choke (current balun) is that it creates a field which couples to the line on the other side, generating a common mode current on the other side. This is exactly the same phenomenon that occurs when you put a common mode choke at the feedpoint of a J-pole or ground plane antenna, or for that matter an off-center fed dipole. You end up with near-zero current at the point where the choke is inserted, but an increasing value of common mode current from there downward, peaking at about 1/4 wavelength from the choke and every half wavelength onward. The most practical solution I've found is to insert a second common mode choke about where the first peak would like to be, that is about 1/4 wavelength below the first choke. This forces the common mode current at that point to be near zero, breaking the resonance of the nearest half wavelength of line and putting the susceptible remaining transmission line farther from the radiating portion of the line or antenna. But compromises or additional chokes have to be used if the antenna is operated on multiple bands.

Roy Lewallen, W7EL

>I was curious about your comment, here we call it "cosas de
>chismosas" (gossipy things?) :>) - Miguel

Hi Miguel,

I presume you mean my comment "no point in that."

It simply means (and ties in with the joke above) that the topic
requires no authority to bless it.

Symmetry and Balance are always referenced to some third element or
characteristic. In our context, it is usually ground. In our
context, ground is also called "common."

No one is really interested in Symmetry and Balance unless there is a
nearby ground or common.

Many, many posters here can present some very confused postings about
balance, what ground is, and what constitutes common mode. You have
already revealed that a lot of your fellow Hams in Argentina (and this
is not confined to any country) are confused about the purpose, use,
design, and need for a BalUn (or BalBal, or UnUn) transformer. Going
further, they (speaking of those many, many posters) are also confused
about what a "transformer" is - thinking it is equivalent to the
iron-core variety.

And on, and on, and on....

> mode current in one part of the line and not in the other, ideal choke
> it is an open circuit to RF currents.

Miguel,

There are two issues.

Firstly, if the common mode choke (or isolator) is physically small with respect to wavelength, and there is common mode current on the line immediately adjacent on one side of it, why is there not an almost equal common mode current on the other side... or explain the current path that allows the first mentioned current AND that complies with Kirchoff's Current Law.

Secondly, the common mode 'conductors' are coupled conductors. I see that Roy has dealt with that, so I will leave it at that.

For these reasons, it is naive to think that a practical common mode choke has such extremely high impedance that the common mode current through the choke is zero, or even near to it. Even if it did drive common mode current to zero or near zero at that point, that does not mean there is no common mode standing wave, just that a node exists at that point.

Ask yourself how whether the use of a common mode choke (isolator) to effectively reduce common mode current between the common mode choke and the tx don't also reduce common mode current between the common mode choke and the dipole feed point.

Where did you get the idea that electrons that are accelerated are a intrinsic part of the diamagnetic material?
The air is full of particles from the Sun looking for a place on a diamagnetic material to rest. The size of these particle is such that a tensile force is applied to a surface and is of the smallest mass possible so the speed of light can be obtained. The force vectors on the surface of the radiater is the surface current and the displacement current which in conjunction supplies acceleration with spin to generate charge in a straight line projection to counter gravity.
Nature loves simplicity does it not?

I might note here that a Trask 4:1 current balun is not a Guanella current 4:1 balun, they have quite different connections. The argument that Trask makes in support of his design on a single core does not apply to the Guanella design.

The key to the answer is in two words in the first sentence of your posting: "immediately adjacent". You're certainly correct that the current can't abruptly drop to zero at the terminator, because of Kirchoff's Current Law. But the current doesn't abruptly end, rather it drops to zero following a sinusoidal distribution curve. It's quite equivalent to a dipole with insulators at both ends and wires beyond that. There's current on the antenna, zero current at the insulators, and some induced current on the wires beyond due to mutual coupling. If the wires beyond are broken by insulators every quarter wavelength or closer, the induced current will be small. But if the wires beyond happen to be close to a half wavelength, the induced current can be quite high. This is almost exactly the situation with transmission lines and chokes, with the chokes acting as somewhat imperfect yet adequate insulators.

Common mode chokes can be made pretty easily to have an impedance of more than 1k ohm. Both modeling and measurement show this is usually adequate in typical installations to drop common mode current to very near zero at the choke location. But you can easily have substantial current a quarter wavelength on either side of it.

This core contains four windings, two on each side, they ARE wound to be two 1:1 current (guanella baluns.) The phase of one winding on the floating side is reversed, resulting in balun voltage being additive for that floating winding, alone.

Anyone with EZNEC, including the demo program, can easily get the value of intrinsic Z of various media. Just define a Real ground type in any model and enter the ground constants. Then open the Utilities menu and select Ground Info. A wave normal to the ground will reflect exactly as it would from the junction of two transmission lines with one having the impedance of free space (about 377 + j0 ohms) and the other having the ground's impedance. The nature of oblique reflections depend on the polarization of the wave relative to the reflecting plane (the ground), but a reflection always occurs whenever the wave encounters a change in the impedance of the medium, or a "mismatch" as Richard calls it.

My modelling experience is that other things like connection to ground,
and open ends to conductors have more influence on the location of a
standing wave pattern than typical common mode chokes.

I have created a simple model of a Carolina Windom at 7MHz, assuming that
the device at the dipole feedpoint is a 4:1 voltage balun with negligible
common mode impedance, the isolater is 1000+j0 (your nomination), and a
feedline configuration that demonstrates that the isolator has not caused
a minimum in the common mode standing wave pattern at that point.

A pic of the current distribution is at
http://www.vk1od.net/lost/Clip043.png .

Didn't work for this case, the current minimum is about half wave between
the isolator (left hand blue square) and the dipole, and the common
current entering the shack (right hand blue square) is quite large.

Apologies, there was an error in the model... I hadn't installed the
source properly. I have replaced the pic at
http://www.vk1od.net/lost/Clip043.png . The situation is a little
different, but the isolator does not force a current minimim at its
location, and the common mode current flowing at the shack is large.

A "4:1 voltage balun with negligible common mode impedance" isn't a
common mode choke, and can't be expected to reduce the common mode
current at its location. If that's what the Carolina Windom uses, I
wouldn't be at all surprised to find in practice what you see in the model.

In no way is a voltage balun a common mode choke or "isolator". When a
load is asymmetrical with respect to ground, a voltage balun actually
forces a common mode current to exist at its insertion point. Forcing
equal voltages into unequal impedances results in unequal currents in

the two conductors. The difference between the two is the common mode current. That's why I've tried for a very long time (at least since the publication of my balun article in 1985) to educate people that voltage baluns are not the things to use in antenna systems.

My comments were strictly regarding the properties and uses of common mode chokes (current baluns), not voltage baluns.

http://www.saunalahti.fi/hohtola/ham/windom/windom-balun.htm , presented
the the DXZONE front.

Both baluns shown are current baluns, ie devices with a high common mode
impedance.

One of the advantages claimed of the Carolina Windom is the contribution
of feedline radiation.

If that was your objective, you would not employ devices (such as the
current baluns in the referenced article) that reduce the commom mode
feedline current.

Of course, the objective is a specious one. If you wanted to minimise
participation by the feedline as a radiator and pickup (especially noise,
since it is often closer to some noise sources), then you might use an
effective current balun. Indeed, more that one would probably be needed
for an OCF dipole.

Roy,

Nearly everyone I have worked and who used a Carolina Windom was using a commercial antenna, expensive as they are here because they are not made locally.

I don't know what they use for the 'black boxes', the commercial devices are proprietary and they don't disclose parameters... but if the seller promotes feedline common mode contribution to radiation (as they do), then a current balun at the top frustrates that.

The 'design' seems to depend on the lower device (the isolator, presumably a common mode choke) to cut the common mode current off and prevent it flowing towards the shack... in the style of the O/C switch someone mentioned, but as we both note, that is not consistent with basic circuit theory principles (KCL in this case). The NEC model I posted shows that a 1k isolator (common mode choke) is not effective for that purpose.

As I said in an earlier post, feedline radiation is a specious objective... but obviously quite effective sales wise.

I did find an article on a home brew 'New Carolina Windom' at
http://www.w5fc.org/files/how-to/QRP%20Expressions_version_1.pdf . It uses
a Rutroff 4:1 voltage balun at the off centre dipole feed point, and high
distributed C implementation of a W2DU style current balun for the 'line
isolater' some distance from the dipole feed point (10' for the 40m and up
version).

The article goes on at length about contribution by the 'vertical
radiator'.

Owen

It is obvious, we are talking about different things. External fields
always will induce common mode currents in conductors, then it is
virtually impossible completely remove it. We will have commond mode
currents in our line if our ham neigbourhood turn on his TX or our
wife talk near with her celluar phone too.

When I talk about interrupt common mode current with choke I am not thinking in prevent all possibles external induction fields over the section of line isolated with the choke but in interrupt the current flow that would have in this point if not were the device placed. In that sense no puntual devices can avoid induction laws. Also, a good isolator it is a capacitor and always will allow displacement currents.

From electromagnetic point of view the inductor field beyond the isolator or ideal choke it is the same that any other external field. Not work either if as isolating device I installed five meters of optical fiber and a pair of transducers :>)
Do you search for a TL incapable to induce external fields?, then we are not talking about baluns, perhaps we could talk about EM shieding of the TL.
Similar situation if we install a perfect balun and run the TL paralel to the antenna, common mode current not depends.

Owen

It is obvious, We are talking about different things. Fields always
will induce common mode currents in conductors, then it is virtually
impossible totally remove it. We also will have commond mode currents
in our line if our ham neigbourhood turn on his TX or our wife talk
near with her celluar phone...
When I (or "we") talk about interrupt common mode current with choke
(or isolator) I am not thinking in prevent all possibles induction
fields over the conductors. The goal is interrupt a current that would
have in a point if the device (choke) it was not there (neither you
hope for ideal behavior, we must be consecuent).
In this sense no puntual devices can avoid induction laws. Also, a
good isolator it is a capacitor and always will allow displacement
currents.

From electromagnetic point of view the inductor field beyond the
isolator it is functionally similar to any other external field. Even
if you install a five meter optical fiber with a pair of tranducers
isolator betewen a line section you can not prevent electromagnetic
coupling. Similar situation if we buy our ideal balun and then we run
our line parallel to antenna :>)

Do you search for a TL incapable to induce external fields?, then we
are not talking about baluns, perhaps we could talk about EM shieding
of the TL.

Hey Richard

I said you, "mismatch" it is a magical word. TL reflected waves also
are explainabe with "mismatch" word. However mismatch it is a name for
a physical phenomena, what is that? When we talk about a traveling
wave reaching the "mismatch" point we can try to explain WHY the
reflection occur. You can talk about electric or magnetic field
collapsing in discontinuity, etc. One step beyond of a magical word
there are another magical words, electricity, magnetism for example,
well that is the matter: to advance in de why's and the how's,
otherwise we had remained in the realm of Newton and Huygens.

Since I don't know how robust the Carolina Windom isolator is, my
following statement may or may not apply to the Carolina Windom.

The above problem goes away *if* the choking impedance is high enough
to *cause* a common-mode standing-wave current node (minimum) at the
choke because the net magnetic field is then near zero on both sides.
The same thing happens when a well-designed trap is placed in a
dipole. The high impedance of the trap at the parallel resonant
frequency causes a standing-wave current node and reflects the forward
wave back toward the feedpoint instead of allowing current to flow
through it into the rest of the wire. Here's the current distribution
on a trapped antenna. Note how the trap impedance causes a standing
wave current node at the trap.

Hmmm....
Something odd here!
When current is a constant as would be the impedance of radiation
alone I find the impedance to be 50 ohms and a ground wave exists.
Thus the question regarding particles at rest on the radiator. Can the
particle skin be classified as a "medium" where a mismatch does not
exist and where the mismatch which does exist is between the particle
layer and the atmosphere?

I calculated the current moment for the model I spoke of earlier, just considering magnitude alone, to get an idea of whether the common mode current was significant. In this case the current moment due to the feedline is just a little greater than that due to the dipole. Just over 50% of the current moment due to the feedline is due to feedline between the isolator and tx.

The conclusions I draw from the model are that:
- the feedline is just a significant in contribution to radiation as the dipole; and
- the isolator does take the downstream feedline out of the picture as suggested by some explanations.

You can try to compare it to those things you mention, but to me, it is chalk and cheese (ie totally different).

Owen

Nobody said the Carolina Windom choke was that robust - just that it
is possible to design a choke with a high enough impedance to cause a
common-mode standing-wave node at the choke.

> Even if it did drive
> common mode current to zero or near zero at that point, that does not
> mean there is no common mode standing wave, just that a node exists at
> that point.

There is a common-mode standing wave on one side of the choke and not
on the other because the very high choking impedance reflects the
common-mode traveling wave on one side of the choke back toward the
source of the forward wave. I took a trapped dipole and dropped a wire
from one end to mininec ground. The standing-wave current is free to
flow through the choke and establish a standing-wave on the other side
- but it doesn't. Here is what a robust isolator is supposed to do to
the common-mode standing-wave current.

http://www.w5dxp.com/trapgnd.JPG

Again, I am not saying the Carolina Windom isolator is that good -
just demonstrating a principle that you seem to be missing above.

Here's a model of a Carolina Windom on 20m with a 2k choke (isolator)
20 feet down the coax from the antenna feedpoint at a height of 50
feet. The maximum current on the coax braid above the isolator is 0.72
amps. The maximum current on the coax braid below the isolator is 0.14
amps. The radiation pattern is close to the advertised one for 20m.

Do not you heard about the kids telephone?
The two cans and the wire. The ions in the wire are the medium for the
acoustic waves.
For the electric waves the medium are the electrons.

The same is with the Sun. The bumps on the surface we see after 8 min. The
auroras after a few days.

Hello,

A large loop does receive more signal, but will also receive more
noise/interference. You should optimize for best signal to noise
ratio. Often, larger does not mean better.

When you make a loop as large as your room, the wire may run close to
mains wiring or equipment that generates interference (that may result
in bad reception). You can better make a small portable loop that
you can move around to find the sweet spot/orientation for best
reception. You can use whatever insulated copper wire to make the
loop.

Best regards,

Wim

Hello Miguel,

I didn't follow this topic for some days.

The two-step approach will work and you are right, "balun" is not a good word for an OCF dipole as a "balun" can also be a center-tapped transformer where the center is connected to the ground of the unbalanced side (voltage type balun). This one will not suppress common mode current in an OCF application.

What you need is a "device" that does the required impedance transformation and accepts large common mode voltage at the high impedance side without introducing common mode current in the feed line.

Regarding the two-step approach, I have a simple "device" for reception. It consists of a 1:3 (1:9 impedance ratio) ferrite auto-transformer (no galvanic insulation). The 50 Ohms side (coaxial) contains a three section common mode choke to avoid common mode current in the 50 Ohms feed line.

Best regards,

Wim

I think that the simple explanation why 'ununs' get misnamed as baluns'
is that, in their wound transformer form, they often look very similar.
It doesn't help that, depending on how it is wound and connected, one
transformer can sometimes be connected to serve either as a balun or an
unun - and, in many cases, also an impedance transformer.

As far as I'm concerned, while I've known the term 'balun' essentially
'for ever', I had never come across the newly-coined 'unun' until fairly
recently. It was probably simply known by its function, ie an 'RF
transformer'. I have to confess that I don't know why 'unun' has become
popular. It's a rather 'ugly' word, and is somewhat difficult to say
clearly. Maybe that's why they get mis-called 'baluns'!

There is absolutely no reason why there should be any real confusion
between a 'balun' and an 'unun' (other than carelessness, or ignorance
of their function). If you want to group them together, they should

probably come under a general heading of "RF Transformers, and RF Matching and Other RF Interface Devices" (or maybe something even more long-winded).

Hello boys (greteengs Wimpi, how are you?

For monoband applications we can get more Z from a coaxial choke
making the winding for autorresonance. K1TTT have a good data table.

Time ago I want test differents antenna to lift with a kite and I
found =>
http://www.io.com/~n5fc/rfd.htm, the idea seems to me interesting
enough to make some test that are descibed here =>

http://www.solred.com.ar/lu6etj/tecnicos/jeringa/la_jeringa_revisada-en.htm

from here I think of another use of de "coaxial trap" to get more Z
from coaxial winding specially in monoband antennas, I named de
critter "The Trap balun" =>

http://www.solred.com.ar/lu6etj/tecnicos/tpabln/trampa_balun-en.htm

4NEC2 simulations and real field test show me both approachs works
fine :>)

How did you arrive at the value of Q (=100) used in the modelling. Was it measured, or guessed?

Based on some experimental work, I expect that the effective RF resistance of a closed space solenoidal coil of braided coax is much higher than the same straight length a copper cylinder.

BTW, if you want to make a more compact self resonant trap on the lower HF bands, wind the coil in two layers. The article at http://vk1od.net/antenna/7MDipole/7MDipole.htm shows a pic of a two layer 7MHz self resonant balun made with IIRC about 6 turns per layer of RG6.

Owen

Good idea. Choose your favorite band for your Carolina Windom and wind an "ugly balun" choke just below the isolator. An "ugly balun" choke is capable of forcing a common-mode standing-wave current node (minimum) on the outside of a coax braid just like a trap is capable of such on a trapped dipole.

OK, I'll ask, "I am correct in thinking that most are using a 'voltage balun' (ruthroff 1:4) as the 'Low Loss Matching Transformer' and a 'current balun' (guanella 1:1) as the 'Special-High Isolation Line Isolator?'"

I mean, logic dictates this to be the best combination ... however, one is best to ask ...

Hi Miguel,

Who is "we?" "Traveling Waves" have their own special meaning, and
that meaning is unnecessary for this discussion.

> reaching the "mismatch" point we

We?

>can try to explain WHY the
>reflection occur.

If you choose, but the WHY is unnecessary too.

Skip the magic words, as you call them. Everything you discuss is
available, by parts, but together nothing changes anything.

A transmission line is an artificial medium. It is artificial in the
sense of being man-made. Being artificial, it attempts to be similar
to nature's available media. The electronics is same for all.
Discontinuities, interfaces, abound in both artificial realms and
natural realms. Their behavior is governed by the same physics - only
the parameters are different (which is the nature of reality).

That is what I am using on a home built version. Using a 4:1 voltage balun at the feedpoint and the ferrite bead type about 20 feet down from the feedpoint.

The ferrite choke is doing something as it gets warm while running around about 1 KW to the antenna. Doesn't heat up when going into a dummy load.

My 'Windom' usually works beter than an 80 meter dipole on 80 meters plus gives me the option to operate several other bands.

Sounds like you must be using A LOT of beads for 80m. Why not a couple
#43 toroids, stacked? Or, a t300-X or t400-X?

Hi Ralph,

Through the 4:1? Probably not, or you would have said so (and
unlikely you have gone to the trouble to build a 4:1 dummy load).

As the dummy load is most likely enclosed and shielded, then that
suppresses common mode currents due to your test transmission.

And, yes, when your ferrite choke (AKA 1:1 BalUn) heats up that is due
to common mode currents that were not snubbed by the voltage balun (by
design - so why choose it?).

Add a second ferrite choke (AKA 1:1 BalUn) at the feedpoint -before
feeding the voltage balun.

no, galileo was right, stokes was wrong. but you might want to join
that anti-galileo group, i think you would fit right in.

One example that's fairly easy to build. You will need a variable
cap for tuning. I don't know what type of antenna you have on
the stereo, but one of those loops can be fed passively just
orienting it close to the loop or loopstick on the stereo.
If it has no antenna, but connections for an AM antenna,
you can using the coupling loop built into the loop antenna, and
run coax or whatever to the stereo.

I am not surprised at your results with a dummy load. If it is a well screened unbalanced dummy load, you should expect zero dissipation in the balun cores.

The fact the balun cores are heating in the antenna scenario indicates there is some common mode current. You probably have no idea of the current.

Something to keep in mind is that the average power of uncomressed voice SSB is about 3% of PEP, so if your 1kW was uncompressed voice SSB, the average transmitter power might be more like 30W, or half that in a 50:50 over scenario over the long term.

Another thing is the ferrite toroids heat and cool very slowly, so the operating temperature might still be rising half an hour after the transmitter is applied (so long as you haven't exceeded their Curie temperature).

It would not surprise me if the common mode choke consumes a significant portion of transmitter power on some bands, the portion will depend a lot on your own scenario.

> Eat your heart out dummy !

I found the problem !!! I have just been twisting wire connections so
it takes time to bed in and lower the resistance. I probably will have
to solder connections before the snow flies so the impedance stays
steady and constant. Next job is to determine how high the frequency
goes before
the impedance or something else goes wobbly.
I haven't got the equipment to go very high so I may just zero in on
some satellites to see what happens.

I tested the bead choke just by going from the amplifier to the dummy load.
I did not have the 4:1 balun in the line with the dummy load. The dummy
load was 50 ohms. I just ran this test to make sure the beads were heating
up and not the coax. It is a comercial bead choke and the coax was about

the size of rg-58. Suspose to be some kind of higher power rated coax good for over 1 KW. I just wanted to make sure it was power on the outside of the coax and not inside the coax. If inside the coax, then it would have heated up while going into the dummy load as has been mentioned by this thread.

The 80 meter dipole and the 'Windom' are at right angles to each other suported on the ends at 50 to 60 feet. In almost all cases the signals are usually much beter on the Windom. It seems the only time the dipole is beter is when the stations are almost off the end of the Windom. Stations around 45 deg to both antennas still give the windom a beter signal.

I was running the amp around 1 KW with a carrier so the power was a constant
KW.
I only felt the choke while testing on 80 meters. It got warm, but not hot
after about 5 minuits of applied power while hooked to the antenna. Never
got even warm just going into the dummy load.

While I don't know what the choke actually does to the outgoing signal, my
reasoning was to try and keep the unradiated power from comming back in the
the shack and causing problems.

Yeah, screw up the windom pattern and see how you like it then! Why heat the 1:1 so far away, heat it at the antenna, 30ft up, then you won't be tempted to check the temp! ROFLOL

> Isolator?'"

That's the theory behind the Carolina Windom. Whether it actually performs up to expectations is questionable. The marketing hype acknowledges that the 4:1 voltage balun will cause common-mode current on the coax which is expected for off-center-fed dipoles. They seem to assume that the "Isolator" located 20 feet from the dipole feedpoint is an ideal device with an infinite choking impedance. If it were that, the antenna would work exactly as advertised. Unfortunately, there's no such thing as an ideal isolator so we are zeroing in on what is possible in reality and what must remain as marketing hype. From my modeling, it appears that the isolator works well for any frequency where the length of the coax from the feedpoint to the isolator is approximately an odd multiple of 1/4WL. That occurs on 20m and 10m. Unfortunately, my modeling indicates that RF-in-the-shack may be a problem on 40m and I would be tempted to add an ugly balun.

I do not remember Owen, I believe Q 100 was a number for the text example, calculated Q on 7 MHz for ideal coil was about 400 and measured real coaxial made coil with a GR-1606 A near 200. at that time I did not think to use RG6, It is more light than RG58, isn't it? Seven turns of RG 58 on 63 mm diameter with parallel condenser it was very light, enough for the purpose, Rokkaku lifted 40 m "syringe" antenna flied very well.

R, to two layers choke. Well... frankly to me common mode radiation it is not something I lose sleep, I have not troubles in my shack and I was not very lucky in all attempts to reduce nasty modern suburban noise with baluns + chokes + grounded points, so many noisy companies and neighbors cables around :>(antenna height showed much better results.

Hi Ralph,

Then the loss is trivial. On 80M the Z should be sufficiently high
enough to prevent a large current to develop a node at that point on
the line - it remains to be seen if you need another one further down
to suppress induced current that would then slide into your shack (you
would be complaining of it by now, however).

Even worse than that! A lot will only consider the loss in the
transmitted signal of such an antenna, perhaps even call it "trivial."
However, the received signal will suffer from exactly the same losses
... while even losing 500 watts of a 1KW signal can be considered
"trivial", losing 50% of ones received signal is NOT!

That depends on the signal to noise ratio. If the signal to noise ratio remains the same while 50% of one's signal is lost, the dynamic range of a low-noise HF receiver usually makes up for it. Witness the Beverage antenna where 99% receive power loss is tolerated: (from Wikipedia)

"While Beverage antennas have excellent directivity, because they are close to lossy earth they do not produce absolute gain (typically -20 to -10 dBi). This is rarely a problem, because the antenna is used at frequencies where there are high levels of atmospheric radio noise."

Cecil,

If a mere loss of 10% drops you too close to the sensitivity threshold
of your receiver, your ability to pull out a weak signal just suffered
the kiss of death ... 100w on a kw might not even be noticed on the
other end ...

As a Windom is only likely to be used on the HF bands (and probably
mainly on the lower HF bands), I would have thought that a few dB of
attenuation would have negligible effect on the SNR.

Good mornig Richard

You are right my friend, there are not conduction currents, there not
displacement currents, there are not electrical and magnetic fields,

there are not electric charges neither electrical dipoles in soil and water, just "mismatch" and "discontinuities" (do explain antenna radiation with "mismatch") I wonder why those evil teachers make me spend my time studying those things. Well... now I will return to my science fiction physics books :) :)

As mentioned in several articles, people have used a horizontal loop as an inverted L, or top loaded vertical, by tying the feeders together at ground level and tuning it against ground. Specifically, I am interested in knowing personal experiences with a configuration of using an 80 meter loop on 160 meters, with the loop 35-40 above ground. Also of interest is how much of a ground plane was installed. I'm interested in only stateside contacts on 160, not DX. If you have used such a configuration, I'd like to hear from you within this newsgroup or directly.

I've been very happy with the performance of my 40 and 80 meter loops and use a weatherproof rapid disconnect, for 300 ohm or 450 ohm window line, when storms approach.

Thanks for reading this posting and don't forget the HF swap nets on 40 and 80 meters.

73,

Evan, K9SQG

I'm not too sure that wire wrapped around a magnet would be that great
at picking up electromagnetic waves - honestly.
I could be wrong, but it doesn't make a lot of sense to me really.
removing the magnet would result in better reception, but the length of
the wire in the voice coil probably wouldn't be nearly enough anyway.

Hi Miguel,

There aren't? You have problems.

> just "mismatch" and "discontinuities"

and more problems.

>(do explain antenna
>radiation with "mismatch")

******** Part One of Explanation ********

What about a conductive antenna is matched to an (relatively)
unconductive air (or free space for that matter)?

When your RF, conducting down the transmission line, sees the antenna,
it finds either a match and continues into the antenna, or finds a
mismatch and is reflected (yeah, some cannot accept the concept of
reflected power - so let's say that the energy does not cross the
interface except by some proportion in degree to the mismatch).

For what RF power/energy that does get into the radiating element, it
conducts down to the end of the element - and guess what? - it stops
conducting further in that direction.

Strange that this has to be said, being obvious in the first degree.

So, we have the antenna with some characteristic Z - can you put a
number to it? We have the surrounding medium with some characteristic
Z. They have some integral (meaning a number, integer) relationship.
Dare I call it mismatch?

When you look at the current distribution along a half wave dipole,
does it not exhibit a standing wave? If there were not a mismatch,
where did that come from?

The field emission is also in the first degree.

> When you look at the current distribution along a half wave dipole,

It the field emision is strong the VSWR is 1 and no standing wave.

Am I right?

Ian,

Ah, the statements in support of mediocrity about.

Yes, there is an element of truth in what you say... but looking at it a little further....

On any bands where the external noise is very much greater than the receiver internal noise, small extra antenna loss will not markedly degrade S/N ratio on receive.

One of the issues when the feedline participates as an antenna condcutor is that its proximity to noise sources (eg the power wiring of a building) may lead to higher receive noise without increasing signal strength, so feedline participation can degrade S/N by that mechanism. You won't see that called out in Carolina Windom adds which claim feedline participation as an advantage.

On the tx side, loss in the antenna system reduces EIRP, and so directly degrades S/N at the other end. So, even on those bands where external noise is very much greater than receiver internal noise, pay attention to antenna efficiency to achieve optimal radiated power to be heard at best S/N.

One of the bogus arguments often trotted out is that efficiency is less important with QRP since there is less power to damage a lossy component. Another view is that if you start out with a transmitter that is 10dB or so behind the average transmitter power being used, then why exacerbate the situation when an even lossier antenna system.

For a once technically based hobby, we do think up some phony rationale.

It is a personal judgement about whether 3dB (mentioned by one poster) or any other number is acceptable in the compromise that is made with all practical antenna systems.

Owen

John, when are you going to give up on this crystal receiver set of
yours and get a decent receiver?

http://crystalradiosupply.com/contents/media/litz%20special%20edition.jpg

For me, receiving at anywhere near the 0.13 uV receiver threshold is
just too much work. I think they should outlaw any received signal
below 1 uV.

No, this form of question "why to ask more?" it is ironic, in spanish means that "you", not me, do not want to ask more. You stop the questioning in a high level (as in software "high level" meaning) useful descriptive model of the world and refuse to look for the underlying process responsible of that. "Magic" for me it is => PRINT "hello world", because beneath it is asm code for PRINT instruction, more deep it is movement of bits inside the processor, more lower yet it is the electricity. To explain all program operations perhaps we do not need go beyond PRINT statement knowledge, but BASIC it is not the end of the story...

Why do you think only you study boundary conditions...? it is the more conventional form to treat the issue of reflections! All this speech to refute accelerated electrolite charges radiation? Do better shows to us why a ion vibrating due an electric field it is incapable to radiate EM energy. Better yet, shows us that you has replicated the paper's experiment and has got nil results. Until today we have only scholastic rationalizations, not "bench work".

I have to think about that question for a while. At the risk of
translation problems,
1. I don't think only boundary conditions;
2. I don't think I am the only one who studies boundary conditions;
3. Boundary conditions are not incorrect solutions.

> it is the more
>conventional form to treat the issue of reflections! All this speech

Were you looking for an answer that refutes electrolite charges
radiation? Are YOU refuting electrolite charges radiation? Are
electrolite charges radiation the only solution? Is there radiation
if there are no electrolite charges? [You have already skipped past
dielectric lensing which refracts radiation too.]

> Do better shows
>to us why a ion vibrating due an electric field it is incapable to

Darn Cecil, quite peeking!

From the crystal silicon in the semiconductors, to the crystaline structure of the metals ... I just can't get away from the darn crystal radios! And, alas, I am afraid, these days, the sensitivity of my receivers front end far exceeds my hearing ... I was just bragging. You caught me!

But, I can still remember those days when I could pull out a gnats whisper above ... but then, as I remember, there was far less noise then.

4080. Coax choke question

Newsgroup: rec.radio.amateur.antenna
Date: 2010-09-16 14:41:32 UTC
From: Bill Ogden <billogden@optonline.net>
Message-ID: <4c922c81$0$31277$607ed4bc@cv.net>
Source record: 7380

I have a half-sloper attached to my tower. It is mostly used for 80 meters (but also for 160 and 40 in rare cases). It is attached to the top of the middle section of a 55' crankup tower. The tower has a number coax and other control lines suspended a foot or so outside the tower. I am in the "far suburbs" but 40/80/160 still have more noise that I hoped and I suspect some of the noise is from the neighborhood; there is no specific noise generator that I can detect.

Question: would a coax choke (5 43-material toroids with 5 loops of coax) at the feedpoint of the half-sloper do any good? I am a little confused since the tower (and, I assume, the outside of the coax) is an intentional part of a half-sloper antenna.

At the bottom of the tower, the coax goes underground for about 50' to the rig.

I can't disagree with anything you say. I'm no advocate of the Carolina Windom, and have no plans to use one.

From the point of view of receiving (and causing) interference, allowing the feeder to contribute to the antenna radiation is certainly something which one should be circumspect about. The various comments and explanations (here and elsewhere) indicate that can be a bit of an art to ensure that the radiating common-mode feeder currents are restricted to where they ought to be.

And while, on receive, a bit of 'unnecessary' loss is usually of little consequence on the lower frequencies, losing transmitter power is not something you want to do, on any frequency (if you can avoid it). But, as always, it is often a balance between performance, convenience, and what you are really trying to achieve with your amateur radio station.

There are two sources of common-mode current. A choke at the resonant
dipole feedpoint reduces the common-mode current conducted onto the
outside coax braid. Unfortunately with the tower being a radiator and
the coax tied to the tower, inducted common-mode is the major problem
and difficult to solve. A choke at the antenna feedpoint will have
little effect on inducted common-mode current. I wonder if you are
frying any earthworms along your buried coax? :-)

> Bill - W2WO

You're correct that the feedline and/or tower are part of the antenna. What you have is a dipole (not necessarily symmetrical), with one side of the dipole being the half-sloper "antenna" and the other side being the tower and feedline. The feedline has two transmission line conductors, which are the center conductor and the inside of the shield. Whatever current flows out of one must flow into the other. The current going to the half sloper equals the current flowing down the tower and outside of the feedline shield. If you effectively choke the tower and feedline currents, you'll also choke the current to the half sloper.

While you can effectively choke the current on the outside of the feedline (it would probably take two chokes, one at the top and one at the bottom), it won't help your noise situation. Whatever nearby vertically polarized noise might have been picked up by the outside of the coax will still be picked up by the tower. If the problem is vertically polarized local noise, the only solution is probably to go with a fully horizontal antenna with a well-decoupled feedline.

Hello Roy

I do not saw this post. I do not know how you make the simulation, I try a similar one changing "Wire Loss" to "User defined" an put there 5 ohm-m.

The "Average gain" results was very bad, as yours, then, thinking of aspect ratio of IEEE antenna paper (and big masses involved in water and soil reflections) I modeled it with 300 mm diameter wire. New Average Gain now was 0.53 = -2.65 dB, pretty near values given in paper.

Ita was approximateli correct my procedure on EzNEC? what do you think about results?

Thank you very much in advance.

Miguel LU6ETJ

PD: I will repeat this post in another point of thread becaus this one it is older.

The conductivity of sea water is about 5 S/m. This is a resistivity of 0.02 ohm-m, which is the value you should enter as wire loss.

Sorry, I'm not sure what result you mean. You can't change the
reflecting angle -- the angle of reflection is always equal to the angle
of incidence. And the intrinsic impedance of a medium doesn't change
when a wave strikes it, reflects off it, or propagates through it.

I wanted to mean to choose the incident angle for possible anothers calculations, Sorry I get confussed with translated meaning of angle in => "Intrinsec Z = xxx at ANGLE of xxx deg, I understood as incidence angle instead of phase angle, here we can not acostumed to write in that form and I translated bad the meaning.

Today I posted another EZ-NEC question about a simulation of liquid antenna based in yours, but I did on earlier thread post point, have you see it?

(Thank for you quick answer)

Intrinsic impedance is a complex number unless the medium is lossless like free space, so the impedance of ground is complex. A complex number can be expressed in rectangular form (real and imaginary) or polar form (magnitude and angle). EZNEC shows the impedance in polar form which includes an angle. The angle is part of the impedance and has nothing to do with any field. Many scientific calculators can convert the polar number into rectangular form if you prefer.

Sorry, it is not my day, I didn't see this answer neither. Ok, TKS, my mistake, now I put 1/5 S/m = 0.2 ohms-m (free space simulation, 0,97 m length, 10 segs) and similar results to bad resistivity but with 50 mm wire diameter now (0,57). Do you trust in this results?, seems more optimistics than IEEE paper.

Thank you for the confirmation. I'll skip the choke for the half-sloper.

I am aware that many hams take a poor view of these antennas. Perhaps I
am a bit lucky because mine seems to meet my minimum requirements ---
especially for transmitting ---
probably because I do not use 80 or 160 very often. (I still need about 25
countries on 80 for 5BDXCC and this is my driver.) I would love to have
a quieter receiving antenna for 80. There is a very interesting scheme in
the
QST I received today; in effect a rotary beam for 80, with variable angle
of reception.

Might, actually, be better to feed the other end of the sloper, bringing
that end as close to the shack as possible, shortening the coax and
dropping out the associated loss, possibly having a favorable effect on
your noise, etc.

Of course the addition of a suitable counterpoise(s) would be necessary
... just a thought ... and, of course, a notable amount of work.

What would be most interesting, and an assistance to your average amateur, is have him tie a string which is somehow attached and held fast but blown in an upwards direction, within the stream of water. Then, you finally have the ability to tune, load and communicate on the proverbial "wet string!" And, vindication of all those who have claimed such in old times ...

One small step for him, one giant leap for amateurs! <yeah!>

Evan,
I've done that with an 80 meter loop. It's far from the 'best' 160 meter antenna, but it can work 'okay'. How well it works (with in limits) depends a lot on how it's erected and the 'ground' you work it against. Too much variation in all that to make a guess about, so try it and see.
Paul

Sorry S* I did not read this post (I have to solve aome problem with
Google "tree view").

When I talked about ions I do it thinking in electrolytes containing
feee heavy ions, not isolators.

My doubts with "mass" are about radiation of heavy ions with low
electric fields. Larmor analysis shows radiaton of ions must be
various orders of magnitud below radiation of electrons at lower
electric fields intensities because its larger mass. We need higher
electric fields intensities to get accelerations capable of radiating
equivalent power obtained from electrons with lower E fields, then I
believe they are not responsibles of useful possible EM radiation in
our conditions.

Athough I have built ionic 50 ohms dummy loads with salt and water,
then, I saw it is possible to establish VHF frequencies currents in
such electroytes, however Larmor equation would dismiss (I think)
efficient ions's radiation from it.

Physics books explain EM wave reflections saying low energy EM photons
can transfer its energy to electrons, and they inmediatily return this

energy at the same frequencies (they not become "excited"), then I think that a possible explanatory mechanism is that radiating charges in electrolyte be simply the not free electrons (not heavy ions) vibrations induced by electric field in electrolite.

I do not quite trust in NEC optimistic results I got, because I do not know if resistivity model includes electrolytic conductors, but this it is only my ignorance about it, not an sustented opinion.

try modeling it without the ground on the far end and see how much
different it is. my bet is that it would be much better on some
frequencies and not any worse performing on most others, though the
impedance may make bigger swings.

For electrons the electrolytes are like the insulators.

>My doubts with "mass" are about radiation of heavy ions with low
electric fields. Larmor analysis shows radiaton of ions must be
various orders of magnitud below radiation of electrons at lower
electric fields intensities because its larger mass. We need higher
electric fields intensities to get accelerations capable of radiating

Stream of salt water is like a mast made of insulator with its surface
sokaked with the salt water.
It is in state of permanent surface breakdown. So the electrons can flow and
the "mast" works like a metal antenna.

>Athough I have built ionic 50 ohms dummy loads with salt and water,

I have not evidences but I can bet that there are the surface phenomenons.

I don't see what this in response to (no quoted material) so I will
wing it with an observation.

Building a ground field (like radials, but more linear for dipoles, or
in this case a loop) as a mat will increase performance (more signal
out).

Richard,
Did you look at #30 in the site index given?
That was the first reference to a "Half Delta Loop" I found. It uses
a ground at the feed point and at the 'far end'. Using a single
conductor to connect those two 'grounds' is a fairly common method of
modifying that antenna. I would have to guess that it isn't the -
only- such modification though.

Hi Doc,

Without quote support for that site, I haven't a clue.

Using a ground at the feed point says nothing, really. What does
"ground" mean? A rod? A screen? A radial field? Any of these will
change the picture considerably (OK, maybe 1dB - sometimes ground is
over-rated).

Here's the original post.

Anybody have experience with the "half delta loop" as shown here:
http://www.qsl.net/va3iul/Antenna/Wire%20Antennas%20for%20Ham%20Radio
Wire_antennas_for_ham_radio.htm ?
I modeled it in EZNEC and it seems to solve my space and support
problems on 80/75, and is decent on 40. Patterns get kinda weird on
20M and above.

Hmmm, Doc is right. Try it an see (seeing there was no ask for how
design variations would impact performance).

Source record: 7324

Hi all...

I've got one of these "squid pole" telescopic fibreglass fishing poles that I presently use for supporting a vertical 20m dipole. Being the highest point on the property, I thought if I could build a nice lightweight antenna to go high up the top of it, it'd work well as a mast for a 2m antenna.

I'm looking for a lightweight antenna, and feedline, suitable for this purpose. I wish to operate around 144.300MHz USB... so horizontal radiation pattern would be better. I get heard perfectly well on a quarter-wave vertical at present, so I think the gain of a loop will be sufficient... but a bit extra height would help a great deal.

The full-wave loop looks almost ideal... nice and simple, apparently good gain over a dipole for an omnidirectional antenna. I have some 300ohm ribbon I can feed it with (RG58 makes the pole bend over... and of course anything low-loss will be unworkable).

The catch is, I'm not sure how to go about impedance matching, with the loop having a theoretical impedance (so I hear) of 100ohms, the ribbon being 300ohms, and a radio that expects 50ohms. I'm not sure how the feedline characteristic impedance will impact on things, being 300ohm... there's no such thing as 50ohm ribbon in the shops AFAIK. I'm not sure this has to match though. The antenna itself though, does need some sort of transformation back to 50ohms.

Giving it some thought... another way to achieve this would be to use two loops in-phase. 100 ohms in parallel with 100 ohms gives 50 ohms. I'm just not certain of the spacing, and how close they'd need to be. I've got the wire cut to make two loops (no idea what gauge... approx 1.5mm diameter solid copper) to a length of 2.08m.

I'd like to know if anyone has an idea how far apart these need to be (vertically) on the pole so that they work together in-phase (or alternatively, 180° out-of-phase... I just swap the connections on one loop... I suspect this will halve the required distance). I could just experiment, but if someone's been there done that, then I'd appreciate their insight.

Regards,
Stuart Longland VK4MSL

One trick I saw on a ham's web site (I can't find the URL sorry) was to make home-made ribbon cable, running conductors through regular spacers. That could be a good option for you simply because you can make it super light-weight, but it also gives you flexibility with the spacing and therefore the impedance.

I'm not qualified to say how loop antennas are normally matched, but I thought that particular idea might be helpful in your case.

Long time no chat! Cheers,

Tom VK7NML

Chapter 17 of the 1962 ARRL Handbook describes how to homebrew
balanced tuners for VHF. I use the 6M version with either a 6M Sterba
curtain or a fullwave 160M loop, works FB. I also built a 2M version
that works well but doesn't get much use as I don't use that band very
much.

Are you intending putting the 2m antenna on top of the pole carrying the 20m vertical dipole? Do you think they might interact?

Not only light weight, but low wind resistance I should think.

The common '300 ohm' TV ribbon is not exactly 300 ohms, or necessarily close to it. You can expect a loss of about 1dB for a 30m run of matched TV ribnon on 2m.

One solution to 'match' the load to the line is a quarter wave transformer... look it up in a handbook or Google for it. It is relatively easy to construct a quarter wave line section of arbitrary impedance on 2m.

At the other end, you are still faced with the challenge of transforming 300 ohm balanced to 50 ohm unbalanced. You could use the combination of a 4:1 half wave balun using coax (50:200) and another quarter wave transformer to 300 ohms.

The thing is that you might not be able to simply design the sections this simply, you may need to make an adjustable impedance transformer of some kind at the tx end. You could home brew a little ATU, or use something like a stub tuner. Even if the TV ribbon operates at VSWR=3, the loss should be acceptable for a 30m run.

This project throws you into the deep end, a project to drive learning about and understanding transmission lines.

There are a lot of different potential solutions, the above is one and others will have other ideas.

Owen

Hi all...

Thanks for the suggestions thus far...

Regarding the tuners in the ARRL handbook... I've got the 1975 edition
here, I'll have a look there.

I think there probably will be some... but hopefully not a serious
problem since only one will be driven at a time. At the moment I've
got a quarter-wave groundplane and a TV-antenna in _very_ close
proximity (about 40mm apart) so surely any interference I get with the
20m vertical will be minor compared to what I (and the TV viewers at
my QTH) already put up with.

Thankfully, I think I'll be lucky if I use more than 10m... 1dB isn't
too bad though, probably better than the equivalent length of RG58.

By the sounds of things... homebrewing a 2m ATU may not seem so
silly... I did make an air-core autotransformer for use on HF which
I'm able to use to tune a short end-fed vertical (actually, a 6' 27MHz
CB whip) quite successfully on 40m... perhaps the same concept will
work for VHF. I was hoping though, if I could hook two loops in
parallel, that would give me 50 ohms... I guess it'll be time for
experimentation.

Yep... A lot of people say "Just buy X brand/Y model antenna"... but I
believe in giving the homebrew route a try first. :-) I live to
learn.

If you want to learn something, make your experiments simple... and that
means separating your experimental antenna from things that will (and
they surely will) confuse things.

Firsly, ask yourself it ATU is a common approach, and if not, why not.

Re the unloaded / base loaded 6'whip on 40m , it is unlikely that it is
very efficient, but there is a lesson there, even inefficient antennas
can be used to make contacts... just less of them. Some people use QSOs
as 'proof' that an antenna 'works', whatever 'works' means.

>
> Yep... A lot of people say "Just buy X brand/Y model antenna"... but I

That was what ham radio was about once, a dying part of hobby now.

Some also say "any antenna is better than no antenna at all", but if you
are interested in the technology of antennas, you will do better than
that.

Good luck Stuart

Owen

I doubt a noticeable percentage of amateurs use wire antennas with a
balanced feed for VHF in 2010. The antenna being considered isn't
commonly used so a common approach to matching might not provide the
most appropriate solution.

The problem is Fritz, that the common HF technique of operating the transmission line at high VSWR and transforming the impedance to that which suits the transmitter at the transmitter is less appropriate at VHF due to increased transmission line loss.

At 2m and above, the technique used more often is to use low loss lines operated at low VSWR, save short sections that might form an impedance transformation function.

That is not to say it can't be done other ways.

Omni directional horizontal antennas aren't very popular on 2m except for the odd beacon and mobile station, full wave loops aren't very often the choice in that case anyway. Nevertheless, the project is a vehicle for learning.

Owen

I think you have hit on the solution. For VHF and above the antennas are usually resonant and the bandwidth is small enough you can match the antenna at one frequency and the swr will be low across the band. There has been an improvement in the coax over the years also. The 9913/LMR400 types have about half the loss at vhf and above as the older rg-8 type.

While it is hard to put up, the G-line may be something to think about at 450 and above if one does want to use something other than coax/hardline.

Most ssb/weak signal stations operate horizontal on vhf. While you may be able to have some fun with a small antenna, a 5 element or more beam will surely help. I did make a contact of several hundred miles on 432 with a 1/4 wave vertical on ssb one time, but that was a rare condition. My rotator for the beam was locked up and the beam was in the wrong direction. Just tried the vertical for fun and it did make a couple of contacts.

The radials need to be tuned when elevated. If you used 1/10 wave
radials, they would have to be loaded to be 1/4 wave electrically,
and I wouldn't expect the performance to be near as good as full
length 1/4 wave radials. And.. the radials need to be tuned for
each frequency you operate. Which usually means multiple
elevated radials for each band to be used.
Myself, I would try to use a longer radiator as well, but a
screwdriver will work.. A longer radiator would work better.
I had a full size 1/4 ground plane up for a good while.
32 ft radiator with four 32 ft radials. The base of the radiator
was at 36 ft, and the radials sloped down at about a 45 degree
angle. I built the radiator from an old 5/8 CB antenna that I
reinforced with inner tubing and lengthened to 32 ft. It was
totally self supporting and require no radials. Pretty light too.
I don't have it up now, but I still have the antenna on the side
of the house.
To avoid radials of any real length the best bet is usually to go
with some type of loaded half wave design. IE: Cushcraft R5,
etc..

Hi Mark,

Of late it seems most questions are of the "drive-by" category with no apparent interest by the OP for responses.

However, I know full well you will engage in dialog - so here goes:

There is no particular virtue in having the radials being resonant on any band of operation IF the entire antenna is being tuned. And such it would be with an elevated screwdriver.

It then becomes something of an academic issue: why not discard the radials and simply think of the elevated Screwdriver operating as a vertical dipole with one end grounded (where the coax rises from below

where the shield is attached to suitable ground treatment)? Just sit on the tune button until the ad-hoc VSWR match is found. That's how Screwdrivers are tuned anyway, aren't they?

Well.. Not quite. But I guess it depends how one is feeding it.
Normally it's tuned by varying the number of turns on the loading
coil, which is motor run. I assume he will have the motor control
at the shack. Normally for the lower bands, you would also use
some impedance matching for a better match to coax. But that
coil or whatever, would normally be at the base of the radiator.
He's basically running a normal everyday ground plane, except
that the radiator is short and coil loaded.
So I don't see it as tuning the whole antenna per say. I still think
the radials would need to be resonant to be effective, and also
do a semi decent job of decoupling the feedline.
>
> It then becomes something of an academic issue: why not discard the

> Screwdrivers are tuned anyway, aren't they?

Humm.. sorta.. But I'd rather have a lower 1/4 wave section to
act as the lower half of the dipole. Or have radials sloping down
at a steep angle to require less room. If it's high enough anyway..
But the usual screwdriver is just shorting out turns in the coil
to adjust. And the impedance matching is usually fixed and
fairly broad banded in operation.
So when you tune the coil to resonance, the match will generally
be good for pretty much the whole band in most cases.
I've never really used a screwdriver, even though I have one sitting
in the garage.. I preferred my plastic bugcatchers so I could
use a higher coil location for more efficiency and better current
distribution.

But what he wants to do, I consider just an everyday ground
plane, except he can vary the coil loading from the shack.
I'd still rather have the full size ground plane myself.
I'm a radio bully.. :) The one I used really worked well for
long hauls on 40 at night. It would smoke my dipoles to DX.
The longer the path, the better it did. The break even point
where the vertical and dipole were about equal was generally
700-800 miles or so. Anything farther, and the vertical got
better. At 1500 miles, usually 2 S units over the dipole..
To VK land, 4 S units over the dipole. The farther you worked,
the better it did vs the dipole.

"I know the S meters are not accurate, but good enough for
A/B comparisons.."
The elevated version at 36 ft and four radials did much better
than the same 32 ft radiator ground mounted with 32 radials.
The improvement elevated was like day and night.
I calculated my four radials at 36 ft were probably about
equal to 60 or so on the ground.
It was very effective for a simple antenna. The only state

side guys that would regularly beat me were either
running bob tail curtains, or yagis's.. They had to be
running multi elements to win. Course, I usually helped
things by running about a KW back in those days.. :)
Don't want to strain anyone's ears over there. :/

Hi Mark,

That was my point about the screwdriver being run as a elevated vertical dipole.

In point of fact, that is how it is designed to work (after a fashion). The bumper mount (or car chassis attachment) is the grounded lower element, then we have a coil of variable length, followed by the upper element with the feed hidden inside the lower element.

I don't see that radials add anything to this. Their radiative contributions all cancel anyway if they are straight out, and they add towards approximating a vertical element if they droop. If, perchance, you wanted short radials (straight out or drooping), then it would only require more inductance to match the capacitive reactance. Push the tune button and walla! (as the french would say), more turns of the coil out there. And for being a sleeve dipole, that coil would be quite high - current distribution would come out in the wash.

So why not just use two screwdriver antennas with each antenna being used as half of the "dipole"? Since Don Johnson was mentioning this being done in the 90's by apartment dwellers, it's obviously been tried before and may even work. It likely won't be the most efficient at getting the most RF out but likely will work.

I note incidentally that homebrew screwdrivers would drastically lower the cost of this experiment.

Sure, you could do this, but there's really not much advantage over a single screwdriver and a fixed element opposite it. Either way, you're basically putting an adjustable inductor in series with the feed. Whether it's symmetric is almost immaterial, especially for a short (relative to wavelength) radiator.

Short antennas look capacitive. Putting in a series L compensates for that, but doesn't do anything about the low resistance at the feedpoint. What most mobile screwdrivers do is put a 4:1 transformer at the feed.. that gets a nominal 12.5 ohms up to 50, the inductance takes care of the reactive component, and you're "good enough".

In fact, it's typically even more clever, the 4:1 transformer has a fair amount of leakage capacitance, so at higher frequencies, it looks more like a 1:1, which works out nicely, since the feedpoint R is closer to 50 ohms with a longer (in terms of wavelength) radiator.

More details and measurements here:
http://home.earthlink.net/~w6rmk/antenna/screwdriver.htm

I think there are better ways to do a space limited antenna.

4140. Elevated vs buried radials

Newsgroup: rec.radio.amateur.antenna

From: Owen <noone@no.where>
Message-ID: <KjPoo.661$hz6.363@viwinnwfe02.internal.bigpond.com>
Source record: 7340

I have been exploring models of a quarter wave monopole over a set of radials on 80m using NEC4 models.

If my models are valid, and they use 'average ground', the indication is that while it may require a large number of buried radials (>16) before efficiency levels off a bit, similar efficiency can be obtained with just three radials elevated more than 100mm above the soil.

This leaves me wondering why the popularity of extensive fields of buried radials for the lower bands.

Comments?

Owen

because they are easier to install in most cases than raised radials,
unless you get them far enough up to walk under them like i do.

4142. Problem matching real Log Periodic to NEC

Newsgroup: rec.radio.amateur.antenna
Date: 2010-09-29 23:36:06 UTC
From: Dave D <xray66@earthlink.net>
Message-ID: <0a7dc1e7-c7cf-4c43-bba7-08f46cb47f25@e22g2000prj.googlegroups.com>
Source record: 7342

Just thought I'd throw this out there to see if anybody had any ideas... I was recently playing with an 800 to 1000 MHz Log design. It came out quite well in the model. It was showing that it should do about 1 to 1.5 average SWR, with a couple little spikes of 2.0 or so. So I went ahead and built it.

Now I know from past experience, that testing logs is very tricky. Unless you have a phase stable cable right up to the feed point, you can get all kinds of crazy readings. But still, you can usually get the gist of what's going on. So I go to test the actual finished antenna, and across the intended range, it's showing SWR as high as 7 or 8, and the best it goes down to is maybe 3. Totally different than the model. As a test, I went to the NEC model and took off all the UHF elements, and just added one VHF element to the low end... It showed around 155 MHz in the model. I did the same thing on the actual antenna and got 1.1 around 153 MHz. So at that range, it's right on. But I am baffled as to why it is so terrible on the UHF. I tried shorting the back end and not shorting. No real difference.

Any ideas?

Thanks,

Because my vertical is located out in a pasture. Deer, horses, and the
tractor will trip over the wires. Even buried, the tractor tires
brought some up when I mowed the pasture late this summer, especially
when I turned over the radial field.

I don't think the model is totally valid.. Partially though..
I agree that for a given number of radials used, slightly
elevating off the ground is better than buried.
But I don't agree that a small number of slightly elevated
radials is equal to a large number of buried radials, and
most certainly not equal to the same number of radials
highly elevated. IE: vs 1/4 or 1/2 wave or more up..
Three slightly elevated radials are not sufficient to lower
ground losses down to a low level over mediocre soil.

I always think in terms of wavelength when calculating
the approximate efficiency of an elevated radial set.
For instance, three radials at 1/2 wave up will be pretty
much equal to about 120 on the ground.
Three at 1/4 wave will be equal to about 50-60 on the ground.
Three at 1/8 wave might be equal to 15-20 on the ground.
Three at cigarette pack height will be equal to about twice
as many as actually used at best. "slightly guessing
on that one, but my real world tests seem to pretty much
agree".
So being as the increase is fairly small at such low heights
in wavelength, it is probably practical to just bury them so
people won't trip over them.. :/
If tripping is no issue, then it might be worthwhile to get
the slight edge in performance. But the increase over buried
will be fairly small with them only 100mm up.

Dear Dave D. (no call sign):

I have found it highly desirable with large and smaller HF LPDAs either to decouple at the feed-point or to choke common mode right as the coax leaves the boom to go down the mast. Of course, one could do both. Once you have cleaned the transmission line, you need to attend to the termination at the end of the boom. Your BW is small for a LPDA so design should be straight forward.

Thanks guys... I've never had that problem before. Any tips for what clamp-on ferrites might work best, or how many? Or the best way to configure them?

I am interested in the electrical performance rather than trip hazard. Once electrical performance is known, issues like trip hazard, mowing, rock etc can be dealt with for each application scenario.

So, back to the electrical performance, do you have measurement data, or can you refer me to articles that contain sound objective measurement data that would suggest that my NEC4 model is not valid.

If I have modelled the situation correctly, the models suggest that the portion of energy lost in heating the soil drops very rapidly with increase in height from zero to just tens of mm, and with very little change to the pattern distribution.

Owen

PS: I perhaps need to clarify the meaning of 'efficiency' in my post, I mean the total power radiated in the far field in the hemisphere, divided by the power input to the antenna.

Distributed capacitance is the enemy of any multi turn balun, whether in solenoid style (eg Ugly Balun) or toroidal winding. You could however try to exploit the self resonance by placing it in the band you wish to use, then the issue is whether the resonance peak in Zcm is sufficiently wide.

The W2DU style ought have sufficiently low self capacitance to operate below resonance at 800 to 1000MHz. I would look to #61 material suppression sleeves, but it may be that a lossier material works for your application.

I meant also to ask how you dressed the coax away from the feedpoint.

I often see pics of coax tie wrapped to one leg of the transmission line spine of the LP. Guaranteed to create common mode current.

Practicality. In most cases, you either want to be able to walk above
the radials, (i.e. bury them or leave them on the ground) or below
them. This means at least 2 - 2.5 m up, and there will be some
sagging. Essentially, your vertical just got that much shorter. But if
what remains is tall enough, it's a great choice. If a friendly farmer
lets you borrow a field in wintertime, stringing four elevated radials
is a lot less work than rolling out 32 on the ground.

Hi Jon,

Noted.

One of the designs I am exploring is an eighth wave vertical over
elevated quarter wave radials, three top guy ropes the the radial
straining posts, and the top section of the guys are top hat wires. The
whole thing is tuned low so that it is matched to 50 ohm line with a
shunt inductor. Modelled performance is within 0.5dB of a ground mounted
quarter wave with 32 buried radials. Elevating the radials with the
shortened vertical is not a big structural challenge, even to 2.5+m to
allow a bit of sag in the radial catenary. (I never said I wanted to rig
the radials at 100mm, just that above that, the efficiency was
relatively high and didn't vary much between 100mm and a few metres.)

But, such a design does not conform to the Rules of Thumb commonly
trotted out for low HF Marconis.

I will look at Rudy's articles, always an interesting read.

Thanks
Owen

People generally don't have the room to have several elevated radials
1/4 wave long for 20/30/40/80m whereas the buried ones can be laid in
any shape required to fit.

I haven't done any careful measurements, but one of the books
I have has an article and graph that pretty much matches the
figures I gave as far as amount of elevated radials needed to
match a certain amount on the ground.
I'm not sure which book it is..
Maybe one of the Bill Orr radio or antenna handbooks..
I don't think it was the ARRL handbooks.
But I have tried exactly what you are proposing. And it didn't
really pan out too well. I could hardly tell the difference between
having them on the ground, and slightly elevated.
Sure, it worked OK, but it didn't mimic a large number of radials
by any means. I also tried the elevated ground plane at various
heights using the same four radials. You could tell an obvious
difference between 1/4 wave up, and 1/8 wave up using the same
four radials. The real world results I've seen seemed to fairly
closely match the graph I have in that book.

BTW, I know it was one of the Bill Orr handbooks which
suggesting trying the elevated low radials.. I think the
same one that had the graph. He seemed to suggest it
was better than having them in the ground. But on the
other hand his graph dealing with elevated radials
suggested the results would be fairly lackluster.
Which they were at this QTH. :(
Now that I think about it, I think it was the Bill Orr
antenna handbook that had that article and graph

pertaining to the radials.

Being as you are talking about radials which are very low,
I assume the base of the radiator will be low also.
Myself, I think a large part of the lack of success I saw
was due to not enough radial density at the base of the low
vertical. I think one would probably be better off taking
the three or four 1/4 wave radials and chopping them into
many short radials and laying them on the ground.
And this is indeed a fairly common practice when laying
them on the ground.

I think having the higher density of wire at the base works
better than have just a few radials elevated. Most of the
ground loss seems to be in the area of the base.
I know metal density under the radiator is quite critical as
far as short mobile whips.
I saw that when I tried mounting my mobile whip on a
piece of angle iron that was running across the bed of
my truck. It didn't work too well, and being I was used
to using that antenna on various mounts, it was obvious
something was wrong. And the angle iron was very
well grounded as far as bonding to the truck.
That wasn't the problem.
I then moved it over to the top of the side mounted
utility bed box, which is a part of the truck body and
a good bit wider, and my usual performance was back.
Just by adding more metal under the base of the whip
did the trick.

I think this is one reason why I always had so much
better results with elevated vs ground mount verticals.
At 1/4 wave up, the base of the antenna was much
farther from ground, and the antenna started to
perform more like a vertical dipole, than a grounded
monopole.
With the ground mount, I was up to 32 radials at
one point. And the performance was still mediocre,
and barely better than my dipole at 36 ft on longer
paths.
Only when I got it up at 1/4 wave did it really come
alive. After that, it ate the dipole for lunch on longer
paths, and with only four radials.
All of my comparisons were done using a full 1/4 wave
radiator.

Anyway, maybe your model is more accurate than I
think. But I've already tried doing that, and wasn't too
impressed with the results.
I've heard others that tried it also, with the same lackluster
results. I think elevated or not, it's just too few a number

of radials to really be effective at that low height in WL.
Too much lossy dirt between the few radials is my
theory.

I just don't believe in too much of a free lunch when it
comes to just a few radials at low heights in wavelength.
My stance comes from actually trying it, vs modeling
it. I don't totally trust the modeling programs in
this area. I've seen too many differences comparing
the models vs the actual vertical antennas.
For instance, using "average" ground, most of the
programs underestimated the performance of my 1/4
wave high ground plane. To get a model that more closely
matched real life vs my dipole, I had to set the ground at
a much higher conductivity.
And in the case you are modeling, it seems to be
over estimating the performance vs real life.
Or at least what I have seen after trying it.

I wished it would have panned out better. Would save
a lot of wire. But for me, the improvement was minimal.
But.. You are welcome to try it. Maybe you will have
better luck than I did.

This topic was investigated experimentally quite some time ago by a
broadcast consulting firm in the US, which generated measured data.
Here is a clip from their paper describing the system tested, and the
results (note that the convention used for "efficiency" here is that
of the FCC practice based on the groundwave field intensity at 1 km
with respect to the power applied to the antenna system):

\\ In November of 1988, our firm supervised the construction of a
temporary antenna system in
Newburgh, New York under FCC Special Field Test Authority using call
sign KPI-204. The antenna
system consisted of a lightweight, 15 inch face tower, 120 feet in
height, with a base insulator at the 15
foot elevation and six elevated radials, a quarter wave in length,
spaced evenly around the tower and
elevated 15 feet above the ground. The radials were fully insulated
from ground and supported at the
ends by wooden tripods. Approximately ten feet above ground, a T
network for matching the antenna
was mounted on a piece of marine plywood to isolate the components
from contact with the lower
section of the tower which was grounded. Power was fed to the system
through a 200 foot length of
coaxial cable with the cable shield connected to the shunt element of
the T network and to the elevated
radials. A balun or RF choke on the feedline was not employed and the
feedline was isolated from the
lower section of the tower. The system operated on 1580 kHz at a power
of 750 watts.

The efficiency of the antenna was determined by radial field intensity
measurements along 12 radials
extending out to a distance of up to 85 kilometers. The measured RMS
efficiency was 287 mV/m for 1
kW, at one kilometer, which is the same measured value as would be
expected for a 0.17 wave tower
above 120 buried radials.

The Newburgh tests gave empirical proof that the elevated system
worked although, in an abundance

of caution, we used six radials instead of four. For the limited time that the system was operational, the
system was stable as determined by monitoring the field intensity at selected locations each day. The
measured base impedance was in general agreement with a tower of this height above a standard,
buried, ground system. Results of the KPI-204 tests were submitted to the FCC in January of 1989.//

I would think that the buried radials are more convenient (broad band, etc.)

Look at the performance of your ankle biting radials when the dimensions
are changed slightly.. For instance, if you shorten them by 5%, does
it make a big difference? For the buried radials, the length is very,
very non critical.

Something else to look at is the sensitivity of "efficiency" (and your
definition of radiated power in the hemisphere/power into antenna is
fine) to soil properties.. if the soil conductivity or epsilon changes
(as it will with changing water content) does the efficiency change rapidly?

Also, what about the loss in any matching components needed (e.g. if you
had a real efficient narrow band antenna, then operating off nominal
means you'll need a different matching network, and the loss in it might
be worth considering)

Thanks Owen,

In this case I had it down the middle between the haves, through clips.

Does that disturb the characteristic impedance of the spine transmission line? If so, does that contribute to the problems you observe?

If this LP is mounted to a mast somewhere forward of the rear element, I would consider dressing the feedline away from the feed point at right angles to the spine, installing a common mode choke near the feedpoint, and bringing the feedline to the mast some distance below the spine.

If you were to perform a test where the LP is mounted a wavelength or more above ground, pointing to the zenith, feedline falling downwards from the feedpoint, common mode choke near the feedpoint, it would reveal whether the array is working as intended. If your actual mounting causes it to work differently, you know where the problem is.

Yes, I understand that there are advantages to buried radials, but I don't understand the preponderance of cases where I see 120 radials pinned on the top of infertile dirt. They still present a trip hazard, and less money spent on just a few elevated radials may perform just as well.

Yes, of course the feedpoint impedance is more sensitive to change in length or conversely change in frequency.

Yes, efficiency is sensitive to soil parameters... for both types, but not very sensitive.

Because of the impedance change mentioned above, the impedance transformation needs adjustment for wide range frequency operation. Not such an issue in the intended application, the DX window on 80m here is just 50kHz.

>
> Also, what about the loss in any matching components needed (e.g. if you
> had a real efficient narrow band antenna, then operating off nominal
> means you'll need a different matching network, and the loss in it might
> be worth considering)

Matching network loss was not included in my analysis because both quarter wave options present fairly similar load impedances that need transformation to 50 ohms. The shortened verticle is slightly lower R

(23 vs 38 IIRC), and slightly more loss can be expected, but it is practical to match with a shunt coil of copper tube and matching loss should be real low in the system context, and in comparison of elevated vs buried radials.

If I haven't got something quite wrong in the modelling, it would seem worthwhile to prototype the shortened version with a view to extending the system to a four-square if suitable.

I have still to read Rudy's papers... I am away from home (less bandwidth) and I will download them later today when I get home. I suppose that the proposed design challenges the norm of a very large number of buried radials. In our case, part of the property is quite rocky, and a configuration with just a few elevated radials offers deployment opportunities that aren't suited to buried radials.

So, my original question is no so much suggesting everyone else got it wrong, but why don't I seem more people doing it this way. Could I be forgive in thinking that the popular, nearly universal, way is to uplift the BL&E research at MF and apply it to 80m?

Owen

The BL&E experiments were conducted using 3 MHz signals, so their
applicability to the 80m band is not a large uplift.

Well, it does different things based on how the cable is routed, but
none are really better than the other... just different. I tried
coming off the back, and also at the mid point... It changed, but not
better or worse overall... The points of good and bad just changed
position across the range.

I'm going to try the ferrites. What do you think about these?

I stand corrected. I have read the paper many times, and my recollection
was that it was below 2MHz. Must be time to read it again!

never underestimate the power of tradition. It was written by BL&E that 120 radials work, and the FCC accepts that for broadcast, so by golly, that's what we do. Why 120? it was at the point of diminishing returns or practicality back when the study was done (e.g. there was no detectable change from going to more)

As for laying on ground.. I think that's more the laying on grass, and eventually, the wire sinks into the grass/turf.

There's also the whole "the radials must be resonant" misconception..

While for a buried radial system (probably because of the losses) it's going to be less frequency sensitive.

Maybe less sensitive for the buried radials? Or, it was "good enough"
for BL&E, so being so written, so shall it be done.

The shortened version will, of course, aggravate the tuning sensitivity.

> the BL&E research at MF and apply it to 80m?

Tradition is a powerful force. Look how many years it took for someone
(e.g. Rudy) to put the substantial work into doing a real quantitative
experiment. For most hams, they're only going to do something once, and
if works ok, that's how it stays. Almost none are going to do a well
controlled A/B study, especially if there's a (not necessarily valid)
tradition that says A works better (where better is ill defined and
probably a combination of radiation efficiency and installation convenience)

Until recently, modeling tools available to most amateurs were not
suitable for making the call, although there have been some people who
did models and published it, but, in the face of decades of "lay down
120 radials" it was a tough sell.

The other thing is whether the difference is big enough to "make a
difference" in observed system performance. For a lot of operators, a 1
dB change in performance might not be noticeable. If you're in a
"either propagation is there, or it isn't" situation the difference
between good and bad is 10s of dB. There are relatively few people who
work at 0dB SNR (where tenths count) on a regular and continuing basis,
and they're not necessarily the ones who are interested in doing

experiments on antennas on the scale needed.

The one question I've not seen asked is how close to what you built is your model? Everything is critical at those frequencies and as little as 1/32" can make a difference. If your model doesn't match exactly the antenna then it's no wonder it's not working as expected. To me modeling the phasing lines between the elements be they separate from the boom or are the boom is one of the trickiest parts. As an example if you used a 1" square boom and modeled it as a 1" diameter wire there would be a problem. They are not equal.

BL&E were measuring ground wave, I think solely. My efficiency measure
is the hemisphere, so ground losses play a different role.

Yes, but the model suggests that the variation in R is very small, and
variation in VSWR (with shunt coil match) is small... in that band segment.

Yes, there will be differing view on what is significant difference. I
am not in the school of declaring less than one or two S points is
insignificant in general.

In the case of a four square in the DX segment, users are looking for
performance... and it seems to me that the elevated three radials, eight
wave vertical with capacity had is very close to quarter wave over
buried radials... depending of course on the soil type.

You mention the modelling tools, I am not so much concerned as to
whether the elevated radials model is good, but whether the NEC4 buried
radials model is good, and likewise for radials on and just above the
ground because those models are setting the benchmark for the
performance of the alternative.

A minor point, but in the interest of accuracy - the greatest number
of buried radials used in the BL&E experimental work was 113.

> There's also the whole "the radials must be resonant" misconception..

While the physical lengths of the buried radials in the BL&E
experiments were stated in free space wavelengths, that does not mean
that those physical lengths will behave the same when buried as they
will when not buried.

As shown in the link I posted earlier in this thread (and by NEC), a
few elevated wires used as a counterpoise in place of the BL&E buried
wires need to have an electrical wavelength of 1/4-lambda for best
antenna system radiation efficiency, even with "short" vertical
monopoles. And even when those elevated counterpoise wires are close
to the earth in terms of a free space wavelength, their electrical
length is not much different than their physical dimension in terms of
a free space wavelength -- as is the case when they are buried.

Theory and practice both show that such wires perform differently when
they are buried than when they are elevated above the surface of the
earth.

you can get rotators to turn a single antenna. the price is probably
about the same, 2 antennas, feedlines, and a switch, or one antenna
and a rotator. it may also depend on what you have to mount the
antennas on.

Hi Jon,

All of the articles are interesting. I have previously read the last, but wasn't aware it was only one of a series.

Looking at Article 3, Fig 1 suggests that efficiency improves very slowly beyond about 32 radials lying on the surface, and 4 such radials are about 5.4dB below 32 radials.

In Fig 2, he shows 4 radials just 6" (150mm) above ground as about 5dB better than 4 radials on the ground.

My interpretation of Fig 1 and Fig 2 then is that 4 radials at 6" are about 0.5dB behind 32 radials lying on the ground. That is the type of effect I was referring to when I said "If my models are valid, and they use 'average ground', the indication is that while it may require a large number of buried radials (>16) before efficiency levels off a bit, similar efficiency can be obtained with just three radials elevated more than 100mm above the soil" in my first post.

Rudy reports some further small improvement (<1dB) in raising the radials to 4'(1.2m).

These are very similar effect to those predicted by my NEC4 model. In the case of my model of radials from 100mm depth to some distance above ground, the improvement was mostly in the range of heights from 0mm to about 20mm. Obviously, the model is sensitive to soil type, and different soil types can be expected to yield different response... but it would seem that just 3 radials at 1 to 3m height give similar system efficiency to 16+ radials shallow buried for a range of common soil types.

I know my interpretation of Rudy's measurements and my NEC4 model don't fall in line with some traditional thinking, and will not appeal to many.

I think it is time to build a prototype.

Thanks for the links.

Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.

The two links below may be of interest in comparing NEC modeling with empirical results.

The first link is a clip from the "benchmark" 1937 I.R.E paper of BL&E, showing that the radiated fields measured 3/10 of a mile from monopoles ranging from about 45 to past 90 degrees in height, and using 113 each 0.412-lambda buried radials is within several percent of the theoretical maximum for a perfect monopole of those heights when driven against a zero-ohm connection to a perfect ground plane. The BL&E tests were conducted in the sandy soil of New Jersey, where earth conductivity was/is 4 mS/m or less. Those measured results indicate those systems were radiating 90% or more of the applied power, and that the conductivity of the earth in which those radials were buried is relatively unimportant.

The second link is a NEC model of a 1/4-lambda monopole driven against four, elevated counterpoise wires with no antenna system connection to a perfect ground plane, showing that its peak gain is 5.15 dBi -- which is the theoretical maximum for a perfect 1/4-lambda monopole driven against a zero-ohm connection to a perfect ground plane.

Adding an ohm or two in the connection from the source to the four elevated radials reduces the gain/field of the NEC model such that it is approximately what was shown in the BL&E study, indicating that a similar value must have been present in their buried radial ground system consisting of 113 each 0.412-lambda wires.

Using NEC-4 to incorporate buried (or elevated) radials into the model should show groundwave fields within 1 km of the monopole that are very close to the theoretical maximum for the applied power when radiated along a perfect ground plane, if the model is optimal, and accurate.

The theoretical maximum inverse distance voltage field intensity at 1 km for 1 kW of radiated power from a perfect 1/4-lambda monopole system is about 313 mV/m.

There are lots of reasons that people don't use elevated radials versus buried ones. But before that, keep in mind that comparing elevated to buried is not really comparing 4 elevated to 120 buried. 120 is overkill, and not many of us who have verticals have that many. I found that 32 was getting into diminishing returns for me, so stopped.

Also buried radials are more forgiving of length variations. My case was that the antenna had to be located a good bit closer to one end of the yard than the other. So the radials on one side were from 10 to 25 feet shorter.

Also, many of us are married, and the spouse doesn't like all that many wires running around. My wife also mows the yard, something that would be relegated to me if I had a lot of wires running around the yard.

And I've used and been around an elevated radial system. It was a royal pain. You have to declare a rather large area off limits, we added little ties to it to warn people, and it didn't really help at night. That experience told me that elevated HF radials was not the way I wanted to go - ever.

Even if you are way out in the middle of nowhere, an elevated radial vertical is a liability unless you put a wire link fence around it - check with your insurance company.

Just my opinion of course, but it seems to be shared by many.

So with the buried radials not being all that much more work,(unless you insist on 120 of them) the greater flexibility of buried radials when dealing with real estate limitations, the appearance and liability issues, just makes a buried radial system a more attractive and practical option to many of us.

I would like to model the Channel Master CM4228HD Antenna with EZNEC.
It looks like a good deal to me at its price.

I need screen to Bow ties distance

length of bow ties

I think the distance between the bowties will be either 1/4 or 1/2
wave (from picture)

I think the included angle in each of the bow ties is about 30 degrees
as pictured.

The phasing lines are obvious from the picture.

There is a picture at
http://www.digitalhome.ca/forum/showthread.php?t=95467

Of course I will share the model!

It may do, I can not comment. My interest is for an antenna for sky wave path, and I have not explored ground wave performance.

In the cases of 32 buried radials and three elevated radials, the patterns are similar, efficiencies are similar, and maximum gain is similar. Reducing the number of buried radials degrades its performance significantly.

The elevated radials configuration allows a shortened radiator with capacity hat with negligible degradation in performance. I haven't modelled the same thing over buried radials, but I expect performance degradation would be significantly worse.

I stand corrected.. thanks..
So they extrapolated to 120 as a "nice round number" for the future
purposes of the FCC.

For broadcasters, sure. But the discussion is in reference to the potential performance difference for ham use, and I would think that there is more than 1 dB variation in the "other end" of the link. The hard core DXer or QRPer digging the signal out of the noise will care, but that's a small fraction of the overall ham population.

yeah, but there's a big difference between 6-12 dB and 1dB.. I think most users would care about 6 dB. Many fewer about 1 dB. And even fewer care about 1 dB AND have the desire and means to perform the experiment in a controlled way. (well, this latter category probably has less than 10 people in it, and only 1 has published in the last 50 years)

Hmm.. and there the real question is what kind of performance are we talking about: the power radiated in a desired direction (Tx) or the ability to null unwanted signals (Rx). Given the generally high noise levels on low bands for Rx, a 1 dB change in efficiency of the antenna might not make any difference for the latter.

A bigger effect on a phased array is the relative phasing. For a 4 element array, you can have pretty big errors in phase on transmit without changing the forward gain much (30 degree phase error on one element might give you a 1dB change). But a 30 degree phase error on receive could turn a -30dB null into a -7dB one..

And for that, the lower loss of your elevated radials might make things "pickier".. that is, as frequency or surroundings change, the reactive term for each element changes, which could change the power distribution and phasing among the elements (depending on the feed system used). (obviously, one of the "current forcing" drive schemes would be less sensitive to this)

The modeling performance of NEC4 for buried wires and wires just above the surface is quite good. Where I would be suspicious is for a wire ON the surface or partly embedded in the surface.

Look for that paper by Burke and Poggio on validating NEC3 and NEC4 (it was published at some conference in Ankara Turkey)

I think you can take the fact that Rudy's measurements match the model
pretty well as experimental validation of the model. indeed, NEC4 works.

Traditional thinking (or more accurately, mindless repetition of
tradition) could well be wrong, eh?

The only reason the FCC used 120, is overkill for the
stations to be able to avoid a costly survey.
If they didn't use 120, they had to do tests to prove
that the system was efficient enough. So most used
120 to avoid all that.
For most cases, 120 is almost twice overkill..
For ham use 60 is usually plenty to get well into
the near optimum range. Any more than that is
a small increase, and usually not worth the cost
of the wire.
Since Owen posted this question, I did a lot more
checking around, and I had already seen the MW BC
examples.
Seems I'm not the only one that doubts that a small
number of barely elevated radials will give a large
increase over ones on the ground.
One that is in my camp is... Yuri will love this..
W8JI.. Tom seems to agree with my stance from
what I can tell. He has done tests in this regard
and his results did not show much of an increase
over the ground installed radials.
In fact, he gave one example where they changed a
MW station from four elevated radials to the usual
buried radials.. I assume 120 of them..
They then had to explain to the FCC why the buried
radials suddenly gave 5 db+ gain over the supposedly
"near perfect" elevated set.. :/
He also did tests on 80m comparing this same thing.

The results did not pan out and pretty much were in
the same ballpark as the results I saw when I tried it.
IE: the elevated radials are slightly better than the same
number on the ground, but only by a small amount.
His tests showed that the usual buried radials using
60 or more greatly outperformed the three or four
elevated radials. By 5 db+..
Myself, I think for four elevated radials to equal even
sixteen on the ground would require them to be almost
1/8 wave off the ground.
So it seems I'm not alone in my doubt of this
supposed free lunch program. W8JI seems to be
in my doubtful camp. A few others too actually.

There might not have been much "discussion" though it is mentioned, but
the summary does contain the following:

"It is also found that a ground system consisting of 120 buried radial
wires, each on half wave long, is desirable".

>>
>
> I stand corrected.. thanks..
> So they extrapolated to 120 as a "nice round number" for the future

It does appear that if someone blessed the number 120, it was probably
BL&E who did it, even if they were talking about half wave radials.

Thanks Jim, all fair comment and noted.

The end application is a four square phased array for the 80m DX window.

The location is at another ham's property, a rural location with ground ranging from dryish clay to rock.

I do expect noise to be lowish compared to residential precincts.

The excercise is really about a design for a monopole that gives reasonably good performance if extended to the four square configuration.

Yes, I note your points about the phase sensitivity to components. That would be a challenge even with buried radials as although we have been in drought for a long time with 'controlled' low moisture content of the soil, rain changes that and the soil is no longer as homogenous.

Nothing is as perfect as a modeller's world, but the discussion and some of the links offered give confidence that a shortened vertical with capacity hat and three radials, and shunt coil matched should give similar performance to full quarter wave verticals with 32 buried radials.

I have just reread Cebik's article on buried radials, and my own models seem fairly consistent.

As you say, Rudy's work is further confirmation allowing for the difference in configuration and the |S21| use.

Owen

Just to point out that for vertical monopole heights of 5/8-lambda and less, the peak elevation plane relative field (E / E max) _always_ occurs in the horizontal plane, regardless of the r-f losses in the buried radial system or counterpoise wires they are driven against, and the conductivity of the earth in which those radial wires are buried, or above which they are elevated.

IOW, the relative field actually "launched" at all angles above the horizontal plane from such antenna systems _always_ is LESS than that in the horizontal plane. The reason for this is related to the r-f current distribution, and its relative phase along the lengths of those monopoles.

NEC analyses showing low to zero relative field in the horizontal plane being launched by a monopole of 5/8-lambda height and less and regardless of the r-f ground they are driven against need to be understood in due context. The link next below leads to further development of this ...

http://i62.photobucket.com/albums/h85/rfry-100/MW_ElPat_Compare.gif

The longest, great-circle, single-hop, skywave paths are related to the relative fields launched by a monopole system at elevation angles of less than ten degrees (see Figure 55 in the link below) -- where a NEC analysis may show very low relative field.

But if such low relative fields really were true for the fields actually launched by such monopoles, then the nighttime skywave coverage of MW AM broadcast stations would be much different than is shown by real-world experience (and applicable theory).

Ken Nist (KQ6QV) has done a lot of TV antenna modelling with EZNEC,
and many of his antenna models (*.ez) are available on this page:

http://www.hdtvprimer.com/SIMS/

However, the CM4228a.ez on that page probably is the old CM4228 rather
than the new CM4228HD. His page analyzing the new CM4228HD antenna is:

http://www.hdtvprimer.com/ANTENNAS/TemporaryPage.html

His main page comparing commercially available antennas is:

http://www.hdtvprimer.com/ANTENNAS/comparing.html

Holl_ands has done a lot of modelling (using 4nec2), including the
new CM4228HD (this page has his 4nec2 model files):

http://imageevent.com/holl_ands/multibay/8bayrefl/cm4228hd

| http://www.digitalhome.ca/forum/showthread.php?t=95467

Also on that site is an entire forum thread for modifying the
new CM4228HD:

http://www.digitalhome.ca/forum/showthread.php?t=103749

John, further searching should turn up more information and details.
AFAIR, the reflector on the new model facilitates reception on the
VHF-hi band, which may or may not be sufficient (it is, afterall,
designed for the UHF band). Too, there are a lot of DIY options...

Best Regards,
Chuck

4194. Grounding An Antenna Question ?

Newsgroup: rec.radio.amateur.antenna

Hello,

I have the normal lightning arresters for my outside (receive only)
antenna, but am still worried.

It has proven just about impossible to have my son to remember to
disconnect my receiver when lightning and thunder is nearby when I am away.

Was thinking about putting in one of those A/B switches (please see:
http://www.grove-ent.com/SWC01.html) that Grove sells in the antenna
line next to my Receiver.

This, being so simple, perhaps he can remember to switch to the Off
position. Maybe ?

I realize that if there is any strike nearby, and it gets thru the
arrestors, this switch being in the off position isn't going to do much
of anything.

But it might help for "low" voltage surges, etc.
What do you think ?

My main question: would it help even more if this Off position grounded
the antenna ?

Thanks,
Bob

well, if your son can't remember then why don't you just disconnect
when you leave. i tried having my dog disconnect, but he has a poor
memory for that also and usually hides under the table when there is
thunder.

otherwise, if you don't trust the lightning arrester you have, why
have it? if it doesn't stop the transient then any switch inside
probably won't either. grounding again inside is also a problem, if
the current is inside already then sending it to another ground
probably won't help, it will just go somewhere else.

Hi Bob,

Research this group through Google for methods of building a grounded antenna: loop, shunt-fed, folded dipole/monopole, etc.

OR

Build an electronic switchable antenna switch (AKA relay) that is only connected to your antenna when someone's butt is planted in the chair.

it's the difference between the effect on a peak vs effect on a null.

consider a simple 2 element array.. for sake of argument, say it's 1/4 wavelength apart and phased 90 degrees, so it has a cardioid pattern.... a gain of 2 in one direction (where the signals from the two antennas align), and a gain of zero in the opposite direction. The gain is 1+cos(phi - spacing*cos(theta)) where phi is the feed phasing, and theta is the direction.. in the preferred direction
1+cos(90 - 90*cos(0)) = 1+cos(0) = 2
in the 45 degree direction: 1+cos(90-90*cos(45)) = 1+cos(90-90*.707) = 1.895
in the 90 degree direction: 1+cos(90-90*cos(90)) = 1+cos(90) = 1
in the 180 degree direction: 1+cos(90-90*cos(180)) = 1+cos(90-90*-1) = 1+cos(180) = 0

Now spoil the feed phase (phi) by 10 degrees... (80
on boresight: 1+cos(80-90*cos(0)) = 1+cos(-10) = 1.984
on 45: 1+cos(80-90*cos(45)) = 1.959
on 90: 1+cos(80-90*cos(90)) = 1.174
at 180: 1+cos(80-90*cos(180)) = 1+cos(80+90) = 1.52E-2

The gain on boresight didn't change much... from 2 to 1.984 (0.03dB)
But the null in the back came up from zero to 1.5E-2.. (instead of -infinity, it's now -18dB)

Change the phase error to 45 degrees...)
@theta=0: 1+cos(45-90*cos(0)) = 1.707
@theta=180: 1+cos(45-90*cos(180)) = .292

So, from the 10 degree error case, the forward gain went from 1.984 to 1.707, about 0.6dB...
but the null went from 1.52E-2 to .292 (from -17dB to -5 dB)..

The thing to remember on any gain antenna is that it takes very little power to disrupt a null (after all, a -30dB null means that if you're radiating 1kW in the forward direction, you're radiating 1 W in the null.. so just another watt will double the energy in the null, turning it from -30dB to -27dB...)

(And, you can see why making antennas with sidelobes <-60dB is VERY challenging...)

Now, change the phasing to, say, 80 degrees.. in the preferred direction, the gain is now 1+cos(10degrees)

Thank you!

I am going to have to spend some time with these. My EZNEC + 5 does not like all of the .EZ files but there is plenty of meat there to be dissected. My interests are academic in the antennas. I don't spend much time watching TV these days.

I have not looked for .ez file examples for a while on the net. When last I looked, most of the sites I found were only interested in selling models. Being an old time frugal Ham I am very cautious with my hobby dollars!

Remember the first set you made from the scavenged parts of old radios and TV's? Remember the excitment of your first piece of old military gear, reworked and placed into service? Remember mail ordering tuning caps, filtering caps, tubes for that first big amp?

Good on you mate! Those were the days when amateurs were hams and men were men--heck, even the boys back then were men by todays' standards!

Sounds like you had it right, did it right, and are still doing it right--to me!

Regards,
JS

I enjoy making my antennas also

But this 8bay hd antenna is pretty cheap. I see it for pick up at 69 dollars
in Toronto. Plus some taxes of course but looks like a pretty solid antenna
for that price. I cannot imagine how much time one would spend getting all
the parts then assembling. I think just too easy to buy today.

Good luck with the build.
I am going to buy two tomorrow, throw them on the tower and be done with it.

I am inclined to agree with you. I expect this to be my recomendation
for the folks around me who are looking for an antenna for HD.

However, there is this young fellow who is bent on building his own.
Given that he just might execute this project and then move on to more
antenna projects, I think I owe it to my early mentors to cultivate
his curiousity.

Perhaps acquiring this antenna and using it's performance as an
objective for diy models will fit well.

I am a Channel Master fan. I don't think you can beat their
price/perfomance in any of their products.

I have explored what you have said in an NEC4 model of a quarter wave monopole with three quarter wave radials at varying heights over 'average ground'. The results are summarised at http://www.vk1od.net/lost/Clip053a.png . The reference for the graph is the efficiency of the same antenna with 120 buried radials in the same soil type.

If the models are correct, laying just a few radials on or very close to the ground (eg the popular method of pinned into the turf) would appear to be a very poor option. The model indicates efficiency improves with a very small increase in height above the dirt, just 30mm is a 6dB improvement of lying on the dirt, just half a metre achieves 90% of the available efficiency.

Owen,

Based upon your findings above, have you thought of increasing the height
of your model to determine at what height would be necessary to equal the
same efficiency as your 120 radial reference?

I don't think it is a simple as that Danny. With sufficient height, the pattern changes significantly and so you cannot compare the antennas on efficiency alone.

It might seem intuitive that a ground plane a very long distance (say km) above earth would approach 100% efficiency, and we tend to assume that for VHF ground planes many wavelengths above ground, the model does not indicate that. At sufficient horizontal distance above flat earth, some rays must reflect off the ground and so warm to soil to some extent, no matter how high the antenna.

The study was more to answer the question whether elevated radials were effective, and how high they needed to achieve similar performance. The model suggests that just three radials at 2m height is about 1dB down on 120 buried radials, or about 90% of the efficiency or EIRP (since patterns are almost identical).

Thanks Owen for the Clip053a.png
The results are just amazing.

But I just cann't understand why the current in the radials, don't
induce a significant current in the earth, that ends as an important
lost power.

Source record: 7160

Dear John: Well said.
Last year, a colleague (also a radio amateur) had his EE class design a UHF (14-52) antenna using EZNEC, then construct the antenna, and then he took the resulting antennas to an antenna range for testing (he had a grant to cover the cost including cost of EZNEC).
The design of an antenna to cover not only 14-52, but also 7-13 is more of a challenge. In this area, we have one station in the 7-13 range. I use a Wineguard HD1080, which is a two bay with extensions on each fat dipole. A second colleague with an antenna that was in bad shape after 30 years, just replaced the old antenna with an Antenna Craft HBU33 with a huge jump in signal and significant reduction in wind load.
Channel Master is good too. Much discussion exists - as has been observed - about the 4228.

Obviously, it is improbable to have an eight bay antenna realize its theoretical gain over the BW needed. I would stop with four.

The picture of the drake amp sure brings back memories from the 70's. If I remember correctly, about 600 watts am was about all you expect from the amp when using a sane drive and 1KW input. (something I rarely did back then)

A solid amp, but was made obsolete with the high power mosfet amps coming out in the 80's. The first homebrew 1KW amp I ran was ~85% efficient, 850w am out on 1KW in ... and if you take filament power into consideration, the drake was simply blown away by advancements in efficiency ...

Still, an excellent collectors item and the one in the pics looks like it was well taken care of ... however, I wonder about the state of the 3-500Z's ... they are getting expensive and in shorter supply, at least around my area.

Sort of.

After you accept that as the objective the clean up involves:
Physical details ... rugged beyond belief, small enough to be
acceptable... maintainable...weatherproof... under daily hurricane
conditions... affordable materials

install issues... different vehicles require a lot of flexibility in
mounting.

I have a project underway where I expect to have a Homebrew T-Match
tuner at the base of a vertical antenna at my QTH. I plan to drive
the mechanics with three $10 electric screwdrivers. Locating the
tuner at the antenna will allow the feed line to operate at a low SWR
which will keep feed line losses to a minimum and rf out of the shack.
Since the contraption will be in the garden shed most of the difficult
aspects of a vehicle mounted screwdriver antenna will be out flanked.

If you sit down and plan it through I expect you will conclude that
the only reasons that you might have to homebrew a vehicle mounted
Home brew Screwdriver antenna is that you have excess time and
materials or you think you can improve on the commercial offerings.

Sometimes my only real motivation is that I have to homebrew an item
before I can fully appreciate the commercial offerings!

BTW, an SGC-237 tuner and a 28 foot whip will tune all of the HF ham
bands automatically and fast! That set up will cost a lot more than a
commercial screwdriver but you can consider that as an ideal
arrangement and compromise your way back from there.

Good Luck,

John Ferrell W8CCW

The feedpoint impedance of a 28 foot whip on 3.8 MHz is ~5-j620 ohms (according to EZNEC) which means considerable tuner/ground losses (~9dB) = not ideal IMO, compared to a 1/4WL monopole. If one wants reasonable performance on 80m, best to stick with not much less than 3/16WL = ~46'.

The Take-Off-Angle of a 28 foot whip on 28.4 MHz is ~43 degrees = not ideal IMO, compared to a 5/8WL monopole. If one wants reasonable performance on 10m, best to stick with not much more than 5/8WL = ~23'.

There's no single monopole length that is optimum from 3.5 MHz to 29 MHz. Just about the best compromise we can reach with an autotuner at the base, IMO, is the 46' monopole for 80m-20m operation or the 23' monopole for 40m-10m operation.

Which is why the whips that SGC sells (and others use) are typically two monopoles in one.. I have fairly good luck with a 9ish foot CB whip with about 25-30 feet of wire roughly spiraled up it. The precise length isn't real critical, as long as you don't wind up with an anti-resonance in a ham band making it hard to match.

The gain effect is the same, but for a lot of radio applications, gain
is important on transmit, but less so on receive, where good back/side
performance (e.g. low gain in undesired directions) is important.

That is, my transmitter doesn't care about a strong interfering signal
from a different direction, but my receiver sure does.

I'll try to get a shot Helmut...

Well, I tried the 61 material ferrites, and it lowered the SWR significantly. No matter where/how the cable comes off, it appears to work best right behind the feed point. Only one of the large 1" ones seems to be needed. I tried adding more, but it didn't really make a difference. It's still not perfect, but it's way better than it was before.

4222. Feed to a folded dipole.

Hi

I'm anticipating converting my coax fed, ninety foot long, folded terminated dipole to a ladder line fed folded dipole, without a terminating resister, fed using an Icom AH-4 antenna coupler. Am I correct in believing that the best ladder line to use for that purpose would be the 300 Ohm type to match the nominal impedance of the folded dipole itself.

Mostly, a TTFD would be used as a multiband antenna. If that remains the case, the folded dipole option is probably not as good as an ordinary centre fed dipole, and there is no special magic to the 300 ohm line.

Speaking of which, you may find the article http://vk1od.net/transmissionline/300/davis.htm of interest, expecially if you intend using it on 80m or below.

Antennas usually are made of aluminum as copper is somewhat heavier
and silver and gold is to expensive. Since lead is now banned in a lot
of places especially with solder you can now buy solder that is doped
with Bismuth !
Now you can't coat your elements with it but if you have a solder
bath you can run copper wire thru it. The bismuth is brittle
but with the underlying copper it is stiff enough to stick it on the
antenna elements. I am assuming that the applied current would travel
along the bismuth coating instead of the aluminum and therefore should
increase gain for antennas that use coupling methods such as the Yagi
tho bandwidth may well suffer some what.
What do you think?

What do I think? I think I'd rather have a platinum antenna! Sure, it would be a lot heavier than aluminum, or even copper. Sure, I'd have to keep it in a bank ... but, I'd still like it!

Regards,
JS

Lead free solder is still mostly tin.

You guys are just nuts to consider messing around with a device capable
of emitting Orgone Radiation!

I mean, you may doom yourself to a life of having to use medical
marijuana to alleviate the migraine headaches and pain! Not even
getting into the heavy genetic damage which is likely to occur!

Is this a multiband application?
If you want to keep all the wires, I'd make it a fat dipole (rather than folded).
Why not put the AH4 at the feedpoint and feed with Coax? The box *is* a bit heavy, but it is weatherproof, and you could run the power/control wires alongside your coax.

I am not sure whether you are considering coating the elements with solder, tin, or bismuth... but they *all* degrade the RF resistance of an aluminium element.

Nevertheless, hams are suckers for snake oil salesmen. Just look at the products sold for antenna wire, open wire feed line and whips... so you might have an opportunity there Art.

Hmmmm!
Isn't the idea to get current to flow on the surface
without the skin depth problem? For instance, when you make a Meander
antenna distributed loads are not existent as they cancel out. This
also means that skin depth is non existant as there is no magnetic
field. Thus there is nothing to prevent the current going beyond where
the skin depth is usually situated where it can continue on to flow on
the surface the path of least resistance.
Now the element resistance is of no concern as it is not now part of
the radiation circuit! Instead of two resistances we only have the
one which pertains to radiation, the sole object of a radiator.
Capacitance and inductance does nothing to advance radiation, tho it
is quite useful to have in other areas of science so why fool with it?
Magnetism and polarization only comes into the picture after
propagation is initiated when particles/electrons are ejected with
helical spin and acceleration which generates various movements,
fields etc after the fact.
Remember, for both transmission and receive the only object that can
break up the parts of electrical and magnetic fields together with
time varying current is the Faraday cage, so it is useful to start
with the cage function to get a true story of radiation. A radiator is
only efficient when you can present a flow path for applied current
where the

source becomes totally resistive.
I threw Bismuth in since it is part and parcel of the superconductor scenario. grin." Super" has many pleasant conoctations for a salesman to use.

you see art, they just don't understand how the magical levitating
solar neutrinos will jump from the diamagnetic bismuth much more
efficiently than from aluminum... and they never will understand until
you can explain how my ferromagnetic vertical antennas that obviously
can't support a coating of your magical levitating solar neutrinos
could possibly work at all.

because the currents in the radials cancel out below them which
reduces the current in the ground. as long as there are enough of
them and relatively symmetric. look at a radial field from below, lay
on the ground and look up at the radials all branching out from the
center... now visualize the current in each one, note that they are
all in phase, the current flows out from the middle to the ends all at
the same time. now if you start adding up the vector representations
of the fields from each little piece you will see that ideally they

all cancel out. in the middle that is likely pretty good, but as you move out from the middle you get farther away from the radials on one side than the other so cancellation isn't as good, but the current is also lower so not as much gets coupled to the ground.

Ferromagnetic materials will work but the diamagnetic vectors get a
bit swamped in competition. Any good physics book will explain that
phenomina or alternatively look up wilkpedia.
Didn't you once state that physics was your major?
Your statements appears to put that as a matter of fiction. Why not
explain radiation from your point of view? You can have your posting
removed after a given time in case you embarrase yourself. Tom where
did all these weirdoes come from ?

no, i'm an ee, not a scientist... my company wanted to change my title
to scientist once, i told them only if i could put 'mad' in front of
it and they let me keep the engineer title. I have to go with the
writings of the masters as mr. b would put it, except i got with the
final set of maxwell's equations as published in books like jackson
and other contemporary writers... which, by the way, do explain that
gauss'es law is a part of maxwell's equations and is a dynamic
equation even without the explicit 't' in it.

Tom, you like many others, feel that your postings are like a private
E mail, but it is not. Your writings
and past postings are available for all to see and judge what sort of
person you are. You continually embarrase yourself. I invite all to
view your past postings to see what manner of man you really are.
As for the Peltier effect that you are referring to, it is you who

needs to check the facts as to who posted that. It certainly was not I. But if you have the real facts then spit it out to show that you know them and can prove it, until then you are spitting into the wind. So Tom back to you. What are the "real" facts that you wish to point to and be specific with respect to the connecting physics for supporting data? You may have a open physics book at your side when responding so you can read up on diamagnetic, levitation, neutrons etc since it is very clear that you were able to jump semesters at will leaving large holes in your educational standing which does not allow you to debate in a reasonable fashion.
OR
You can continue with verbal bullying without
contribution or follow up discussion with other members of the group.

So what is your point exactly? Are you holding on to
radiation by "waves" instead of "particles" or what?
What is the specific relevant law of Gauss that you are referring to?
Show me specifically what Jackson states so I can get a handle on the
specific problem in question. I have no idea what is troubling you
whether it be levitation which you call "magical", "Neutrinos" which
occupy every cubic metre in the atmosphere on Earth. Or, the "double
slot" experiment which opposes a particular law of Gauss. Spit it out
specifically and I and the rest of the group can then discuss it. As
an aside, Gauss's work is in the form of cgs units which are not the

same as Maxwell's units so you have to be careful as how you explain
"this matches that" in your response when and if it comes up.

With respect to the works of the Masters which one could include the books by Jackson and others.
They all state that Gauss;'s law on MAGNETISM
was included in Maxwell's laws or equations on radiation. I know of no text book that outlines the connection between ":statics" and the equations of Maxwell. A debate was held on this forum on the connection between statics and Maxwell which was held in denial by all. After a year or so the statement was made that" the Jackson book outlined the connection between Gauss and Maxwell" so the connection of statics was wrongly connected to the Gaussian law on" magnetics" and not his laws on "statics.".
The boundary laws of Maxwell which is the basis
of all of his equations are also those of statics which, when made dynamic, are the one and the same equation arrived at by Maxwell . I know of no mention in any book on radiation that equates as fact that classical physics mathematically supports the position of particles as the root of propagation which is in agreement with Einsteins laws on Relativity. Point being that mass is required for "acceleration of charge" as with particles./ electrons
and to my knowledge has not been stated as the Gaussian connection to Maxwell..... anywhere!
I would appreciate it if you or anybody can point to where I am in error and where your position can be determined as credible.
Regards
Art.

WOW! Another one of those which you always wondered about, but were too ashamed to ask about. I just knew there were others like me who must have wondered about it. Now that you have just tossed it out like so much fact ... I realize I was silly not to have asked.

We are much better off for having had you share that with the group.

Many thanks,
JS :-)

The model results do not support the common Rules of Thumb (RoT) or explanations that I have often seen on the subject of elevated radials.

The model suggests that as the 3 radial system is lowered, efficiency (meaning total power radiated in the hemisphere divided by power input) changes little until the radials are 100mm above ground, and the efficiency drops quickly, more quickly as the height approaches zero.

I interpret that to mean that there is little elecric flux in the soil due to antenna currents for this configuration until the radials are very close to the soil, and then the loss effects grow very rapidly. I assume that the losses are mainly due to dielectric effects in normal soils, but that might be different if you had magnetic material in the soil.

Is this surprising? I think that if you wanted to make a device to warm soil by dielectric heating using RF, you wouldn't expect it to be very effective if the conductors weren't very close to the soil.

Using more radials reduces the losses.

If you can visualise the electric field flux in the case of the monopole over three radials, and compare it to a horizontal dipole, you may get an insight to why a low dipole is more effective at heating the soil.

Owen

In reality are the continuous flow and the oscillatory flow. Flow of the
particles. The oscillatry flow is the wave.
In the ink printer works the oscillatory flow. In antennas and the space
also.

All monopoles need an electrical reference point to be "driven against."

Using a symmetrical arrangement of two or more 1/4-lambda-resonant, horizontal wires elevated sufficiently above the earth provides that by acting at their junction under the base of the monopole as a point with constant electrical characteristics with respect to the current flowing in the antenna system.

NEC shows the peak free-space gain of such a system using a 1/4-wave monopole to be the same as that of a 1/2-wave dipole in free space, e.g., 2.15 dBi. When that system is operating within a few electrical degrees above a perfect ground plane then the peak gain rises to 5.15 dBi, because all of the radiation is re-directed/confined to one hemisphere.

Horizontal wires lying on, or buried several inches below the surface of the earth do not have the same electrical characteristics or function as when they are elevated. Instead, they serve to collect the r-f currents generated by the displacement field radiation of the monopole -- which currents flow in the earth out to about 1/2 wavelength from the base of the monopole.

If the earth was a perfect conductor then those currents could travel through the earth without loss, and a single, short ground rod would serve as an electrical reference point for the r-f current flowing in the antenna system. The sum of those r-f currents flowing in the earth around the monopole, and collected by that ground rod will be equal to the base current in the 1/4-wave, series-fed monopole. The gain of this configuration is 5.15 dBi, the same as when using a few elevated, resonant wires as a counterpoise.

But the earth is not a perfect conductor. For that reason it is necessary, when using buried radials, to install enough of them in the surface area out to about 1/2 wavelength to collect those r-f currents before they have traveled through much of the lossy earth to reach those wires.

The benchmark 1937 I.R.E. paper of RCA's Brown, Lewis and Epstein showed that 113 x 0.412-lambda buried radial wires used with monopoles of about 45 to 90 degrees in height produced a radiated groundwave

field when measured at 3/10 of a mile that was within several percent of the theoretical maximum for a perfect monopole radiator with a zero-ohm connection to a perfect ground plane -- and this despite the fact that earth conductivity at/near their test site was not better than 4 mS/m.

As an aside: NEC analyses for far-field conditions show an elevation gain of zero in the horizontal plane for a monopole over real earth, and peak relative field gain at some elevation angle above the horizontal plane. However the radiated, relative fields that exist at, and relatively close to the edge of the near-field boundary of the radiation hemisphere of all monopoles of 5/8 wavelength and less are very nearly equal to the cosine of the elevation angle -- which value is 1.0 at zero degrees (the horizon), and zero at the zenith. If they were not, then the fields measured by BL&E would be much different than they recorded in their 1937 paper.

It is only after those fields propagate a significant distance over a real earth path that they depart significantly, and progressively more significantly with distance, from the relative fields described by the cosine value of the elevation angle.

RF

Obviously a reduction in IR losses will improve any antenna. Art how
much do you thing making an antenna out of silver instead of aluminum
would reduce the IR losses.

CORRECTION: change "5/8 wavelength" to 1/4 wavelength.

Jim

Yes it is a multiband application. Why would I use an Icom AH-4
antenna coupler on a single band antenna? What would be the
advantage to wiring it as a "fat dipole"?

As to why not put the coupler at the feed point I would point out that
the statement "The box *is* a
> bit heavy," would pass as a masters dissertation in understatement. An entire center support would have to be created or I would have to rig a catenary at the present support points and lower the antenna closer to the ground to permit the catenary to take the weight of the antenna coupler. I would point out that this present Folded Terminated Dipole is not Tilted but instead is rigged as a flat top. Height is might; so the old radio axiom goes; so I would rather not have to lower the antenna just to avoid using ladder line. Additionally in order to compensate for the bending of the trees that support the antenna now I would have to rig a second counterweight and puller system to keep the antenna itself from being torn apart since the first one would be in use to keep a constant tension on the catenary. That is a lot of work in order to avoid the use of some ladder line that probably has a lower loss than the additional coax that would replace it.

Yeah, I too some of that from my neighbors yard, tried to make an antenna.

Cops came and took me away.

When I asked them why, they said it was none of my Bismuth.

InfraRed loss in an antenna?

or perhaps:

Iï¿½R Voltage Loss in an antenna?

or perhaps:

Iï¿½ï¿½R Power Loss in an antenna?

****

Yes, Iï¿½ï¿½R loss is the entire point (and positive characteristic) of an
antenna, especially if R is radiation resistance.

Hmmm, Iï¿½R loss could be said to be a naturally occurring fact of life
along the length of any antenna if we consider the distribution of
potential.

Ouch, InfraRed loss could burn you - but it would be curious to note
that if an antenna is truly an equal performer (transmit/receive) what
would we hear from the antenna when the sun rises in the morning?

As to the receive-mode phenomenon of this sunrise observation, if that
antenna were coated with diamagnetic water (dew), then we would
observe particles leaping (-um- steaming) off of it (with sizzle)!

Seems you have it backwards. The slow-moving free electrons oscillate
back and forth at HF, moving forward and backward very little
(calculate it for yourself). The energy flow from source to load is in
the form of photons/fields/waves traveling at the speed of light
which is impossible for electrons. As far as ham radio antenna
functions go, electrons and photons are the only things known to
physics to be active in transferring and radiating RF energy.

Symmetrical back and forth take place only in the simple equations.
In EACH wave the forth is stronger than back.

First consuming Ayawaska and then putting on a 3d pair of glasses
actually allows you to see the photons shooting out from the antenna. I
believe it is the "time dilation effect" from the Ayawaska which is
responsible for this, seemingly, "superman ability" occurring.

As always, first consult your local shaman or witchdoctor before taking
Ayawaska ...

Revision: 1.2 2009/11/25 14:41:01
Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team. We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |
rec.radio.amateur.moderated |
rec.radio.amateur.space |

We are willing to provide any technical support necessary to get this
article updated and automatically posted again at a regular interval.
This would include establishing contact with the original maintainer for
any necessary permissions. We would prefer to seek a new, dedicated
maintainer at this time, rather than start auto-posting the original
article ourselves.

For more information about our newsgroup, see:
```

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to
rec-radio-info-request@panix.com.

In each radiator is a stream of electrons. The oscillating pump is in the
transmitter. But where is the tank with the electrons?

It is in the buried or elevated radials. R. Roy wrote: "If the earth was a
perfect conductor then those currents could travel
through the earth without loss, and a single, short ground rod would
serve as an electrical reference point for the r-f current flowing in
the antenna system. The sum of those r-f currents flowing in the
earth around the monopole, and collected by that ground rod will be
equal to the base current in the 1/4-wave, series-fed monopole"

The soil is different in each place. The air is similar. So the elevated
radials are universal. They catch the electrons from the air.

4276. Reed Relays ? (a bit off topic)

Newsgroup: rec.radio.amateur.antenna
Date: 2010-10-07 18:58:38 UTC
From: Bob <rgsros@notme.invalid>
Message-ID: <i8l595fgn1@news.eternal-september.org>
Source record: 7226

Hi,

A bit off topic, but I figure you folks are the true theorists out there, and would probably know about this.

Am thinking about purchasing a shortwave defined radio receiver from WinRadio (http://www.winradio.com/home/g33ddc.htm).

Here is copy from part of their spec sheet:

"The receiver's robust front-end is equipped with an ultra-high-linearity amplifier which results in exceptional strong-signal performance. This already robust front-end is further enhanced with a user-selectable preselector that can operate either in a fully automatic or user-configurable mode. As many as 119 different filter combinations can be constructed by the user (91 bandpass, 14 low-pass and 14 high-pass). The front-end employs 34 subminiature electromechanical relays (rather than often used but distortion-prone semiconductor switches) to ensure high dynamic range."

Was really surprised to see: The front-end employs 34 subminiature electromechanical relays (rather than often used but distortion-prone semiconductor switches) to ensure high dynamic range.

I am retired now, so haven't kept up withese things, or the state of the art nowadays, but are they still using electromechanical relays for front ends feeding a 16 bit A to D ?

Haven't semiconductor switches, caught up with reed relays for this application by now, or do they "still" provide a lower "on" resistance, etc. ?

Any thoughts would be most appreciated.

Thanks,
Bob

I have a lot of SW radios and amateur gear. When you have used a SDR, you are simply left with one question, "Why would anyone, anywhere, use anything different?

I mean, it is still fun to fire up an old one and watch the tubes glow ... nostalgia, I guess.

Forgot to respond to this part ... my whole experience with repairing electronic gear has been, first suspect a mechanical problem (switch, ground, etc.), then suspect a capacitor, then a resistor ... dead last is a semiconductor ... it is taken for granted that properly engineered equipment is the point of discussion ...

Regards,
JS

Propigation is always good on the internet. With a fast (15mbit download)
internet connection why bother with a radio at all?

To be honest, I often don't. I skype chat, I call people on a VoIP phone,
I email, I use facebook, I watch TV from around the world, I listen to
radio from around the world.

TV and radio are especially nice because I can get the programs I want when
I have time to pay attention to them.

I also use my radios because I want to. I expect different things from them
and chalenges to get them.

To answer the original post, reed relays are relatively cheap and have very
high isolation between the poles. Electronic switches are available and cheap
but not with as good isolation (at least not at the price of the relays).

Actually from a manufacturing point of view it sounds like they have taken the matching board from a "100 watt" automatic tuner and converted it to a preselector/filter board by chainging the programing on the controller chip.

In this case the "the front end ...." stuff is marketing hype.

If they got enough of them as a close out, it would be a cheaper than having to make one from scratch, no matter what was in it.

Excuse me, Bob, but no where in the description do they mention reed
relays. I really doubt they are using reed relays because of the open
capacitance of the contacts, plus, reed relays often stick shut
because of fatigue, static electricity, and if left closed for a long
time, metal migration will stick them closed.

Bet they are using regular relays, but in miniature form.

Paul

YES! i have done that and it works great... even better than
bedsprings because you can make it vertically polarized by feeding in
the right place.

> antenna coupler on a single band antenna?

Because the wire length was fixed for some other reason (installation
convenience) or you wanted to operate over a wider band than a regular
dipole would be acceptably matched for..

(mostly because you suggested having the AH4 in the first place)

What would be the
> advantage to wiring it as a "fat dipole"?

Wider bandwidth of the underlying antenna, so potentially lower losses
in the tuner.
Redundant wires in case one breaks.
Less modification of the existing antenna.

Semiconductor switches have issues with intermodulation, etc. and power consumption. For wideband RF, you're not going to be using cheap 4066 CMOS muxes.. if you need to handle strong signals, that implies decent diodes with a fair amount of current.

High quality sealed relays are inexpensive, very reliable, etc.

Tom Horne wrote:

> As to why not put the coupler at the feed point I would point out that
> the statement "The box *is* a
>> bit heavy," would pass as a masters dissertation in understatement. An entire center support would have to be created or I would have to rig a catenary at the present support points and lower the antenna closer to the ground to permit the catenary to take the weight of the antenna coupler. I would point out that this present Folded Terminated Dipole is not Tilted but instead is rigged as a flat top. Height is might; so the old radio axiom goes; so I would rather not have to lower the antenna just to avoid using ladder line. Additionally in order to compensate for the bending of the trees that support the antenna now I would have to rig a second counterweight and puller system to keep the antenna itself from being torn apart since the first one would be in use to keep a constant tension on the catenary. That is a lot of work in order to avoid the use of some ladder line that probably has a lower loss than the additional coax that would replace it.
>

OK.. makes sense.. So you'd have antenna in the air, open wire line to
tuner which is sitting on the ground or somewhere convenient, then coax
to the rig.

As for loss.. open wire line is lower loss when matched than coax, but
in the highly mismatched case, the loss might be greater than the loss
of the coax, if you move the tuner.

This is kind of unintuitive, so we'll run some examples

What's the feedpoint Z of a 90 foot dipole in the various bands?
using W9CF's online loss calculator with 33 ft of 450 ohm window line
For 3.8 MHZ (24-541j), loss is 1.3dB (tuner sees 13.3-15.5j)
For 7.2 MHz (29+768j) loss 0.79 dB (tuner sees 11.6-247j)
For 14.2 (124-681j) loss 0.51 dB (tuner sees 135-663j)

For comparison 33 ft of RG-8X has .17 dB of loss (matched) at 3.8MHz,
.25 at 7.2, and 0.35 at 14.2

Now, the question might be, what's the loss in the tuner matching
29+768j to 50 ohms (tuner at feedpoint) vs loss in tuner matching
11.6-247j to 50 ohms (tuner feeding 33 ft of 450 ohm window line to antenna)

W9CF's tuner applet says 0.3 dB for the first case and 1.7 for the second..

SO..
Tuner at feedpoint at ladder/coax transition
Loss in 450 ohm line 0 0.79
Loss in Tuner 0.3 1.7
Loss in 50 ohm line 0.25 0

Total: 0.55 2.49
That makes the tuner at the feedpoint almost 2 dB better..

Similar numbers for 3.8MHz
24 -541j 2dB tuner loss to 50 ohms + 0.17dB feedline = 2.17
13.3-15.5j 0.9dB tuner loss + 1.3 feedline loss = 2.2 dB

pretty much a wash

---- take home message>> 90 feet is probably a "bad" length to use for this application
---- take home message2>> open wire line is only low loss when well matched.
---- take home message 3>> it's worth it to put the matching network at the feedpoint, when there is a large mismatch.

Running a quick NEC4 model of a 90 foot dipole 10 meters off the ground

So I wrote that antennas are made of metalic conductors, salt waters and
live tree. It seem that material is not important.
The key factor is the oscillating, nonsymetrical flow of electrons. We need
the tank, the pump and an antenna. May be with or without Bismuth plate.

The key factor is the generation, by the oscillating electrons, of RF
photons/fields/waves (traveling at the speed of light) .

The implication by many is that the radiation particles or electrons
are extracted from the actual radiator.
Where did this notion come from and what is its justification?

Really good relays are available at very low cost today. Like less
than a dollar each! Between the Low Pass filter and the inboard
antenna tuner my TenTec Jupiter there are about 30 relays.

Other than overrall circuit size and switching speed I see no
advantage for semiconductors as compared to relays.

As far as "Why Ham Radio instead of internet?" :
I worked Japan last night (not my first time) on PSK-31/20 Meters with
40 watts and off the side of the Beam. The feeling was not unlike my
first Ham Radio contact 50 years ago....

It is my kind of getting high!

I have been faithfully using a coil of coax as a common mode choke for a while without any idea if it is really doing any thing.

Googling turns up more url's than I can follow. I would appreciate any suggestions as to how might measure the effects of the common mode choke. 30 to 17 meters is my favored range of operation. I have a pretty well equipted shack.

Take one piece of wire;
loop it into a half-dozen loose turns (1" diam);
connect a Red LED to the wire ends;
place loop around coax;
slide it along the coax for a distance of something more than a
quarterwave length of the frequency under consideration.

How bright did the LED get anywhere along that length?

You would not be alone. They seem to be the most popular suggestion for dealing with common mode current issues, but I suspect it is often a case of "fools rush in where angels fear to tread". The anecodotal support for Ugly Baluns is not convincing, and quantitive measurements explain why.

They are cheap, and it is the only factor I see consistently shaping recomendations, cheap rather than effective in the application. Of course, doing nothing is cheaper, and better value if it is as effective!

> Googling turns up more url's than I can follow. I would appreciate any
> suggestions as to how might measure the effects of the common mode
> choke. 30 to 17 meters is my favored range of operation. I have a
> pretty well equipted shack.

Well, I better not give you any more references to follow.

The so called 'Ugly Baluns' are so popular, and peform so poorly. They achieve very high choking impedance around a narrow region about self resonance. If you have a narrowband application (eg single band antenna) AND arrange that self resonance at the band of interest, then they are capable of excellent peformance (very high choking impedance).

If your need is broadband operation, look to ferrite cored baluns.

As far as measuring common mode current goes, people have described common mode current meters, and some are available commercially. The problem is that common mode current is a standing wave, and a single measurement (at a single location) says very little.

The indirect effects of common mode current are not so easy the 'measure' as such, but you can asses the impact by things like sensitivity of line VSWR to line length and placement / routing, RFI to ham shack gear, other household equipment, neighbors equipment etc. You might also try to assess degradation of ambient noise due to common mode current. Distortion of transmitted pattern is more challenging to assess.

there is no justification, just mr.b's delusion that is even worse
than your levitating neutrinos. He thinks that its the actual
electrons that jump off the antenna and flow to the receivers.
Now ain't that a gas?

Well we do have opinions exceptpenniokio but where is the backup data?
I would imagine that some old timers are getting near the end of their
antennas life, as what started with a thick radiator has now got down
to a couple of mills and drooping
and only a few electrons left.
On the other hand it is well established that billions of particles
inhabit every cubic metre on earth and the question is that if we
don't allow these particles or neutrinos to settle or rest a dense

fog is going to envelope the earth killing mankind and allowing the dynasaurs to come back. We already have some dynasoars in the making on this thread!

Just a note ...
The signal that will make a switching diode go nonlinear will be Strong signals (mostly AM/FM/TV) that are not even in the desired band. Several receiver manufacturers even place a 20db BCB BP filters as the first thing after the antenna connection and before the attn circuit (also diode controlled)to prevent these signals from even reaching the first BPF diode switching network. A bad thing for people interested in BCB-DX.

I think relays in the front end of any RX is a good thing. Relay reliability has improved allot in the last 30 years too so longevity should not be an issue in a receiver.

Bob,

you made an easy question and a difficult (for me) question.

The easy question.

> Haven't semiconductor switches, caught up with reed relays for this
> application by now, or do they "still" provide a lower "on" resistance, etc. ?

The problem of using diode-based switches is not in their higher "on" resistance, but in the fact that, even if strongly forward biased, they do not behave linearly, like a pure resistance. So, in presence of strong in-band or out-of-band signals, they can create intermodulation products. Increasing the diode forward biasing improves the situation, but the intermodulation performance of a mechanical contact anyway remains superior. Accordingly, some of the latest state-of-the-art transceivers (e.g. ICOM IC-7700) boast the use of mechanical switches instead of diode-based switches.

The difficult question.

> I am retired now, so haven't kept up withese things, or the state of the art
> nowadays, but are they still using electromechanical relays for
> front ends feeding a 16 bit A to D ?

I would re-formulate your question in this way: which is the point of avoiding the use of diodes OUTSIDE the A/D converter, if the A/D converter chip anyway includes switching diodes INSIDE it. This question is to be put to somebody who is familiar with the internal electrical design of A/D converter chips, and knows whether their internal structure is such to cause intermodulation products in presence of strong signals.

Ma Bell used them in the millions with 99.999% up-time.

>because of fatigue,

We are talking about a switch rated in the 100 Millions to Billions of
operations.

>static electricity, and if left closed for a long
>time, metal migration will stick them closed.

That is true with issues compounding this, but as the receiver has its
own spectral display, problems will be shown to you directly.

>Bet they are using regular relays, but in miniature form.

Which would suffer the same issues you offer above.

Reed relay usage design is not for the faint of heart, but when
properly matched (an ugly word here) to the load, then they can
provide service beyond your (and your children's) lifetime in this
application.

In the oryginal Hertz dipole electrons jumps accros the big gap with the
high frequency. Calculate the velocity.

Electrons do not need go-between. Electric waves are in substances and in
the plasma (rare plasma in space).

>The implication by many is that the radiation particles or electrons
are extracted from the actual radiator.
>Where did this notion come from and what is its justification?

Electrons are expelled in the result of the voltage doubling in the end of
an antenna.

The transmitter create the pulsatin flow of electrons.
"Unsteady flow is present in man, machine and nature. The flow of blood in
arteries and capillaries in the human body is pulsatile- composed of a mean
flow superposed with an oscillating component. The tides that wash in and
out of rivers, harbors and estuaries are unsteady flows with very long
periods of oscillation. Many engineering devices employ pulsatile and
oscillating flow. Pulsating flow is defined here as a periodic flow with a
net displacement of fluid over each flow cycle. Oscillating flow is defined
as a periodic flow with a zero mean over each cycle."

"a periodic flow with a net displacement of fluid over each flow cycle"
needs a tank of electrons. It has many names: ground, counterpoise, radials
and chassis.

Now ain't that a gas?

It seems that you do not know too much about the pulsatile and oscillating
flow.
"Unsteady flow is present in man, machine and nature. The flow of blood in
arteries and capillaries in the human body is pulsatile- composed of a mean
flow superposed with an oscillating component. The tides that wash in and

Look at "Simplest Crystal Radi" in:
http://hackingwithgum.com/2009/06/08/how-crystal-radios-really-work/

There is the antenna, diode and ground. Is there the "pulsatile electron
flow "?

If the transmitter produces the AC current and at the end of the antenna the
voltage is doubled and the field emission take place is there the "pulsatile
electron flow "?

In radials no voltage doubling so the field emissions take place only in one
end.

Is it too dificult for you. You are an engineer.

The challenge is to read the material and lose the stuff that is just plain wrong. When you find content that is wrong, it damages the credibility of the whole paper.

To demonstrate how poorly common mode current is understand, the following is a quote from MFJ's web site page describing their MFJ-835 twin needle "RF IN-LINE CURRENT METER, BAL.LINE, 1-30MHZ, 3AMP":

"How do you detect imbalance in open-wire or ladder line? By measuring and comparing each feedline wire current -- your feedline is balanced if the currents are equal."

Well, the line is balanced if the currents are equal in magnitude and opposite in phase (ie 180° out of phase). The MFJ-835 compares ONLY the magnitude, and it is true that if there is zero common mode current, a properly calibrated MFJ-835 will indicate balance, but it is NOT true that if the MFJ-835 indicates balance (equal magnitudes) that there is necessarily zero common mode current.

You will find articles on the net where authors have expounded the perfection of their station using the MFJ-835 as proof of zero common mode current, some even explaining how they continuously monitor balance (apparently at a fixed point in the line). The instrument is not suited to the job, and their results are flawed. The articles would make a good read if they weren't flawed.

>how does the electron know if it is at the end of an antenna wire or
the end of a radial wire?

The first sensible question.

"Radials and Counterpoises have two basic purposes:
1. To improve the RF ground conductivity for the ground current return path.
Unless you live in a salt-water swamp, your ground conductivity makes a very
poor path for the return of ground currents. This increases the ground
losses and reduces the efficiency of an antenna that needs a good RF ground.

E. More radial wires are generally better. As the number gets larger, they
improve the RF Ground less and less, to the point where there is no
difference when adding one more radial to a system that already has 120
installed. Minimum systems of as few as 4 wires can provide an acceptable
ground and increase the antenna's efficiency by a significant amount.
Generally, 6-8 radials is the minimum that should be used." From:
http://www.sgcworld.com/radialstechnote.html

As you see in the radials are many ends. There is the lower voltage and
almost no radiation (electron loss). Radial work like the receiver antena
(caught electrons from air)

Without the radials your stations can work only in a "salt-water swamp".

yes, but how does the electron in a single radial know it is at the
end of a radial and not double as opposed to the electron at the end
of an antenna that does double??

In each end the voltage has tendency to be doubled (standing wave). If you
have radials and the LED you can measure the voltage. It will be lower in 10
radials than in 6.

>as opposed to the electron at the end
of an antenna that does double??

You know what to do to have low VSWR. Low VSWR means that the voltage is so
high that the intensive emission of electrons take place.

At higher voltage the emission or sparks make low VSWR.

oh, so it does double at the end of a radial.. that is different from
what you said earlier.

oh, so the swr changes with transmitter power? that is an observable
prediction that is obviously false... go back to square 1 and start
your theory over again.

If you believe ANYTHING that was published by SGC, you need to go back
to school and relearn everything you ever thought you knew about RF
Antenna Systems. There is a reason Don Stoner, left the company decades
ago, and PeeAir couldn't design his way out of a Wet Paper Bag.

Yes.

I think the write up on K1TTT's site will satisfy my curiousity and
find its way into my Permanent Reference File...
I still need a little more time.

BTW, I think my next lesson will be to understand Hairpin Matching. I
plan to start with the page on your website. If I get stuck I will
bring it back here!

So many fun things to learn, so little time!

We are discussing on the pulsatile flows of electrons and emission of them
from antenna end at transmitting.
At receiving the pulsative flow is in the oppsite direction.
Do you agree?

Existence of the standing waves was shown by Oliver Lodge. They are in each
wire.

Here no new theory. Pulsative flow and the field emission are very old.

Is the pulsative flow of electrons in antennas?

My page shows how to do it more thay why it works.

If you are interested in why it works, consider an L network to transform a 20+j0 ohm antenna up to 50+j0. Think of a hi-pass configuration (series C, shunt L), and find values for C and L. Understanding the L match is essential to truly understanding the hairpin or beta match.

When you have worked that out, you will realise that you can create the series capacitive reactance by shortening the antenna (DE) a little. Yes, that also changes feedpoint R, but only very slowly compared to X.

The inductive reactance could be supplied by a coil, but at VHF it is more practical to use a s/c stub (which is the hairpin).

Back to how rather than why, if you use 4NEC2 to model antennas, it displays a parallel equivalent of the feedpoint impedance. If you shorten the antenna so that the parallel equivalent is 50 ohms // -X (Y=1/50 +j/X), then the hairpin has to supply X (B=-j/X) to cancel the -X (B=j/X).

Another application of the same concept is to shorten a loaded 80m mobile whip (which has low feedpoint R) so that the parallel equivalent is 50 ohms // -X, and shunt it with an inductor of reactance X to cancel -X.

Owen

no, the flow of electrons stays in the antenna and is sinusoidal...
they do not jump off the antenna.

4335. help with wireless video link

Newsgroup: rec.radio.amateur.antenna
Date: 2010-10-11 00:47:30 UTC
From: zeb7k@hotmail.com
Message-ID: <41cd08e4-4829-4578-8d16-392b6a969d98@z25g2000vbn.googlegroups.com>
Source record: 7085

I'm a pretty green in this area so I thought I would ask the
enthusiasts:

I want to set up a wireless video link between my house and a
construction site 1000 feet away. The area between is heavily wooded
and hilly. I want to use a regular non-IP analog CCTV camera with 520
TV lines of
resolution. A 2.4GHz transmitter/receiver pair of 2 watts is my guess
as to the link I will need. I will probably try powering my camera
with a car battery.

What bothers me is that I've searched eBay up and down and cannot find
a setup like this that uses anything more than a 420 TVL camera (and
usually eBay has everything).

My questions are:

#1 Are my selections of frequency and power feasible? What would the
advantages of the 1.2GHz or 5.8GHz bands be?

#2 Am I bumping up into some bandwidth limit with a 520 TVL camera?
How come I am not finding any higher-resolution long-distance
offerings?

Thanks.

In a cristal radio is the diode. The electrons flow from the antenna to
ground. Where they come from?

>they do not jump off the antenna.

They must do it in the transmitting antenna.
They are members of "pulsatile- composed of a mean
flow superposed with an oscillating component".

In reality no "sinusoidal...". The forward motion is always stronger than
the back.

"... for a copper wire of radius 1 mm carrying a steady current of 10
amps, the (electron) drift velocity is only about 0.024 cm/sec". At
100 ns per RF cycle, the above electron moves back and forth about 10
nanometers, i.e. it doesn't "flow" anywhere except at DC.

At RF those electrons never make it from the antenna to ground and
instead essentially vibrate in place. The only thing that flows at the
speed of light is photons/fields/waves. The slow-moving vibrating
electron carriers form a bucket brigade for the fast moving photonic
energy. That fact of physics wasn't fully understood until the field
of quantum physics matured. EM fields and waves turned out to be
particles that are photonic in nature.

I like it when there is mutual agreement. Damn man, you aren't worth the "paper" you write on ... I just love watching you go about it though ... keep up the good work. <wink>

You are the best lesson in getting BS to float which I have ever witnessed. Seen some good ones, but I will admit, you are top of class!

Carry on, stiff upper lip, all that ...

Amateurs have had a long standing of being "American Pie", of being of the backbone of America. I know a lot of us where Boy Scouts, Girls Scouts, had a great respect for the American flag, God, country, family, etc.

I think we should take our radios, our antennas, and any other items which we can support our country, our family, our friends, and our fellow American citizens with ... what say you?

I think lines are being drawn in the sand ... I think we need to decide what sides we stand on, don't you?

And, I am sorry, to go off topic ... please accept my apologies.

Regards,
JS

I have a Realistic DX-160 0.15-30Mhz Solid State Communications Receiver for which I want to build or obtain an antenna.

I can buy 500' of 14awg twisted strand insulated copper wire from Lowes for $40. Then what? I have two trees about 200' apart I could get the ladder and string the wire. Would that work?

I used to have a dipole antenna but it never seemed to make any difference. What component is in the nodes, anyway? A capacitor? A resistor?

In the meantime while I try and figure it out, I'm working on acquiring an 8' ground rod. Plus grounding the coaxial.

Is this radio even worth an antenna?

What about a vertical mast antenna? I don't need to transmit, just receive. How good do those work?

Is a wire antenna best strung E-W or N-S? I want Europe, not Spanish.

Apparently the end of the wire can act as a node to a wave 2 or 3 times as long as the wire. The length of the wire can divide into waves 1/2, 1/3, 1/4 etc. the length of the wire.

http://mypeoplepc.com/members/jon8338/math/id39.html

All I know has taught me I know nothing. Jon

>no whirls... the mathematical operator is called curl, but it does not
relate to the often pictured whirl or vortex.

The math is for the geometrcal description.

In Maxwell hypothesis are the molecullar vortices. The line of force rotate.
Around the wire are the rings like the Helmholtz smoke rings. The line of
force can rotate continously or oscillate. Nothing flow along the line of
force. Maxwell did this model for the transverse waves. They are in solids
and the math is used for the torsional vibrations.

Next Heaviside did more simple math for the TEM. It is tought as EM. But I
dont understand it.

Source record: 7105

You will probably receive lots of suggestions about your antenna. My comments are:

1. Longer is not better. Once an antenna becomes too long, it becomes more directional (in odd ways) and may have more tendenacy to overload the receiver. On the normal shortwave bands, receiver sensitivity is not the issue (assuming a reasonably practical receiver); the signal-to-noise ratio is the key element. A longer antenna can increase the signal but it usually also increases the noise to the same degree and this does not accomplish anything (except possibly overload the receiver).
2. A preselector can help prevent overload and may be a reasonable idea on a less expensive receiver. (But it is not necessary; try working without it.)
3. A vertical or horizontal antenna (or a combination) can work. A horizontal antenna may be less prone to "static" in your area.
4. Does the receiver have two antenna input terminals, with neither "grounded" to the chassis? If so, a dipole might be appropriate. More likely, it has a single terminal possibly with a second terminal optionally "grounded". In this case, a single wire to the antenna might be better. (The "feedline" to the antenna is part of the antenna also; try to keep it away from electrically noisy things.)
5. With a single wire antenna, try the receiver with and without a "ground" connection. It will probably be better with the "ground". You are unlikely to need a ground stake. Try connecting to the "third pin" (ground) of your electrical socket. Or, try two or three wires of different lengths (15 - 25 feet) laying on the ground (or under a carpet, etc). For receiving only, you can try many different things --- there is no "right" answer.
6. For listening on typical shortwave bands, an outside antenna wire perhaps 35-40 feet long should be sufficient. For what you describe, the compass orientation will not matter much. If possible, have the antenna up at least 30 feet and a little away from the house.
7. You did not ask about a feedline. For a single wire you could use coax. What might be better is twin line with the antenna end of one side of the feedline connected to nothing. The receiver end of this "nothing side" would be connected to the ground terminal of the receiver.

All my suggestions will be shot down on various technical points, but they may be reasonable for getting started.

Possibly the most important thing is to start understanding shortwave propagation. What times are best to listen for Europe on which shortwave bands? There are no definite rules here; the condition of the ionosphere varies from day to day and hour to hour.

You would be better off using 900 MHz, as the penetration thru trees
and terrain is better than at higher frequencies.
eyespyvideo.com has all the necessary components, including
transmitter, receiver, antennas, cables, camera, etc. They have
cameras with the resolution you desire. Use the highest gain antennas
available at each end.

Accch! Look what happens when I take a weekend off!

Okay now. I have the N3LI legal department working overtime now.

I am the person who invented the particles leaving the antenna theory. Not Art, in fact I declare prior Art, or even prior to Art.

Ive posted it before but probably before you joined the group, so here goes.....

The process of electromagnetic communications is all based upon tiny little turds that reside on your antenna. Very small turds they are, yet very powerful.

While transmitting, the little turds jump off the antenna, fly into the atmosphere or aether, and then eventually land on a receiver's antenna, completing the circuit.

This is why it is important to transmit every so often, so that your antenna does not gain too much weight. During solar maximum, inactive Hams often have their crappy antennas fall down.

Near the ocean the situation is worse, ya gotta transmit even more often, lest ye be shoveling s**t against the tide.

And it is a well known fact that antennas that are used more for transmitting take on a much higher polish, because there are less little turds, and everyone knows you cant polish a.... oh never mind.

Anyhow, despite some twisted language, it is obvious that these particles are a mer attempt to subvert the original and correct theory.

I have problem with the Faraday effect:
http://www.teachspin.com/instruments/faraday/index.shtml

"Although Michael Faraday discovered this effect in 1845, it wasn't modeled
quantum mechanically until the 1960's. These theoretical calculations are
too sophisticated for the undergraduate student, but an excellent simplified
QM model is carefully presented in David Van Baak's AJP paper. (D.A. Van
Baak, Resonant Faraday Rotation as a Probe of Atomic Dispersion, Am. J.
Phys.64 (6) June 1996)"

In Maxwell's model inside of the solenoid are rotating wortices and they
rotate the plane of polarization.

In Heaviside's model inside of the solenoid is a flux. Do you know
(understand) how the flux can rotate something?

you don't understand that the faraday effect relies on a material to
do the rotation. the magnetic field itself does not cause the
rotation it only aligns the molecules such that the polarization of
the light is affected. you could just as well ask how can your hand
rotate something when you turn a polarization filter or piece of
feldspar with your fingers. if the material is not present the light
does not rotate, and there are no vortices.

4362. J pole question

I can't see that it makes much difference, but is there any deference which way the coax is connected to a J pole antenna. Is it better to have the centre of the coax connected to the main element or the stub?
I notice that most if not all J pole designs on the net have the centre of the coax connected to the main element, however when I refer to a 1977 ARRL antenna book it has it connected the other way.

Is there any difference?

It is doubtful that one is better than the other, though the various proponents are usually adamant that there is only one 'correct' way.

A better method is to feed the coax inside the tube at the centre / bottom of the U section, and have it emerge at the feedpoint where you bond the shield to tube at the emergence, and take the centre conductor directly to the other side and connect it. Not as adjustable, but this method incorporates a balun.

You can get nearly the same effect by strapping the coax to the outside of the tube and bonding the shield at the bottom of the U section (as well as at the 'feed point' of course)... but no one seems to do it. Not surprising, as it is a measure to reduce common mode current which most J pole devotees pretend does not exist.

Owen

Owen
Every set of instructions I found when I was building my collinear J-
pole included a BalUn in the design. Some of the users of these
antennas are not fanatics but simply find it easier to use six turns
of coax as the the BalUn. And as to why it is simply easier to
apply. Since I am getting to the place were I don't like the
inelegance of the coax BalUn I will soon be changing over to a ferrite
bead BalUn for the sake of it's lesser ice collecting properties, it's
improved appearance, and smaller visual profile. Not everyone
believes that the antenna that they are using is magic. Many have
other reasons for not doing it in a particular way. Other than the No
BalUn voodoo are there other reasons that you don't like J-poles?

It is not that I "don't like J-Poles", but that they have certain characteristics that should be considered in their design and implementation.

They are an 'end fed' antenna, and there is necessarily some common mode current excited on the feed line / supporting mast structure. A balun helps to reduce that, and I described an integrated balun that is an elegant construction, though a further ferrite current mode choke would be of benefit.

The plumber's delight construction which is often hailed as an advantage is actually a frustration when trying to reduce common mode current.

Though the J-Pole is often promoted as a easy thing to implement, they figure disproportionately in online forums with questions like "I adjusted my SWR real good in the shop, and when I raise the thing, the SWR changes". The common sensitivity of measured SWR to antenna position and line placement is a sure sign of high common mode current.

The common mode current doesn't necessarily stop them working, but it does frustrate setup, a trap for the inexperienced.

BTW, J-Poles are not popular commercially in this country, I cannot recall ever seeing a commercial J-Pole for non-amateur use. Perhaps there is a message there about convenience and predictability for the installers.

If a J-Pole suits your requirement, go for it. They warrant an effective common mode choke, if for no other reason than to make VSWR less dependent on the layout below the feed point.

The big question I have always had regarding the balun was are we reducing performance by eliminating feedline radiation? For a lot of antennas, that may be a big part of the antenna system.

For shorter wavelengths, like 2m, feedline radiation is bad news for
the radiation take-off-angle. It essentially makes the antenna a lot
longer than 5/8WL, i.e. end-fire, sending most of the radiation up at
a high take-off-angle.

Claiming feed line contribution to radiation as a performance factor is usually a specious claim, and more likely to be made by someone with a commercial imperative than a genuine interest in radiation performance. You know, if you can't solve a problem characteristic, call it out as a feature.

In this case, feed line radiation would usually skew the pattern upwards, not necessarily a desirable feature, probably not desirable in most situations.

I don't disagree, but certain antennas - the EH antenna comes to mind, which resemble a tuned circuit on a stick. Get rid of the feed line radiation, and you almost get rid of the whole antenna. But like you say, its a "feature".

It's also not good practice.

> In this case, feed line radiation would usually skew the pattern upwards,

Not too desirable. Thanks for the clarification. Mine was a general sort of response, not limited to this antenna.

I have an application, as part of a bugcatcher antenna, where I would like to run a number of wires, maybe 6, to the coil as connections to taps, and run them at an approximate 90 degree angle to the coil.

Will these wires have much of an effect? I'm going to try it regardless, but it might be good to avoid something that is obvious to the more seasoned Ops in here.

Hi Mike:

I would try it. I remember vaguely of a commercial mobile antenna that
did just that. If I remember correctly they mounted the switch on a
bracket on the coil to keep the connecting wires as short as possible.
It will be hard to keep the bugs out though.

Or get pretty close to up to date with "QED", by Feynman.

"So now, I present to you the three basic actions, from which all the
phenomena of light and electrons arise:

-Action #1: A photon goes from place to place.
-Action #2: An electron goes from place to place.
-Action #3: An electron emits or absorbs a photon."

I know what is in books. I am interesting in the reality. Now I know that in
a cristal radio the electrons flow from an antenna to ground because there
is the diode.

So in a transmmiter station the electrons must flow (pulsatile flow combined
with the oscillations) in the opposite direction. Could you detect it?

You are confusing the impulse (photonic) flow of EM energy, with the
electron carriers which move hardly at all at HF. Hint: Electrons
cannot move at the speed of light yet we know that EM energy moves at
the speed of light.

In a somewhat similar manner, the impulse energy in a tsunami wave
travels a lot faster than the water molecule carriers which move
mostly up and down. Tsunami waves are hardly noticeable in the open
ocean.

the reality is what is described in the current texts used in
colleges. and no, you can not measure a net flow of electrons in a
transmitting antenna.

After the PAQSO party,my loading coil was incredibly full of bugs.

I'm hoping that I can at least avoid the constant trips outside to
change taps on 75/80 meters. The antenna performs well, but that sharp
tuning can be an issue.

Air particles move at speed of sound. For this reason the speed of sound is
temperature dependent.
The same must be with electrons. Do not confuse the mean velocity with the
max. In air the mean speed is also close to zero.

>In a somewhat similar manner, the impulse energy in a tsunami wave

So they should be taken from the ground, send in the ether, land on a
receiver's antenna and flow to ground, completing the circuit. Is it
possible to detect it?

If it's good enough for an antenna tuner (MFJ-949E) then it should be
good enough for a loading coil. After all, the same amount of power is
involved.

sure, put your antenna in a glass bottle, seal it in with good glue so
nothing can slip out that way... then transmit, the inside of the
bottle will instantly be covered with little turds so you won't be
able to see the antenna any more... case closed.

Most loaded antennas that are very short for the frequency will be sharp tuning. If the tuning is very broad, it is usually an indication of a lossy antenna system

Hi Mike,

Run those wires to what? What length wires?

> Will these wires have much of an effect?

Sure. Will it matter? You (the reader who performs this aside from you, but including you) wouldn't necessarily know where the antenna would have resonated to begin with, and any change could hardly surprise you in that regard. Aside from issues of resonance, we would consider loss. As you are running them at 90 degrees (the ambiguity has me wondering, do they spoke into the coil, or out?), then you are seeking to avoid wire spacing issues that force Ohmic loss through proximity. Given that, loss would seem to be a non-starter. If the wires are long (again, the ambiguity of where they go), then they become part of the radiator, and as such would intercouple. As the entire construction is a wild card in resonance, this would not seem to be problematic anyway. On the other hand, it could diffuse control and present some odd tuning characteristics. This would only add to the lore and you might be able to call it the Beneficial Coslo Effect and we are blessed with the BCE 'Tenna (I won't use the full word, as doing that will depreciate the legendary value). As we all know, any new name inherits at least 6dB gain in performance.

> Water molecules move mostly horizontally. See:http://en.wikipedia.org/wiki/Stokes_drift

What percentage of water molecules are moving more horizontally than
vertically for what percentage of the time? That percentage is
certainly pretty small. Even for those normal steady-state waves, it
appears that the vertical motion at the surface is still greater than
the horizontal motion for at least half of the cycle. *Anywhere except
at the very surface, the vertical motion is obviously greater than the
horizontal motion*. But the subject was a transient tsunami wave where
the horizontal motion is virtually non-existent because of inertia.
Thanks for the example that proves my point.

Borders aren't the problem, where are the secure borders in America anyway? Not that mulitibillion dollar fence between mexico and U.S., that has more holes than swiss cheese. And not the border between Canada and U.S. that is more micky mouse than any other country in the world. Only concerned about taxes.

So borders aren't the problem and the west really should increase its population by allowing more in to bring more manufacturing and jobs to the west. You will all want to protect your high paying jobs, however as Amateurs know the world got smaller and things have changed. Why doesn't the west change with the times?

The original poster here is just a thumper, with no economic knowledge, no biblical knowledge, but raises a good point, the west does need to remove its borders so the country's econonomy can rebound. We need cheaper labor in other words. The more people the more the price is reduced.

Initial idea is to run the separate wires as taps on the coil. I'm intending to run them on the outside of the coil, probably separated about an inch away. The wires would then go to a (insert whizbang gadget here that I'm still figuring out) which then switches taps as needed. I'll probably start with manual switching. There is also the matter of that tuning coil at the bottom of the antenna to ground, which varies between 8 turns of number 12 on a 1.5 inch diameter coil on 75/80 meters, to no coil at all on 20 meters, which is the highest frequency it will tune at.

The antenna itself is semi-standard bugcatcher, a four foot bottom section, followed by the six inch coil, (standard GLA systems) followed by another roughly foot and a half section, then a 16 inch Capacity hat, then a spring and topped off with a 102 inch whip. Taps at the present

short out the remaining coil below themselves. The whole thing is mounted on the spare tire holder - the spare resides in the back of the vehicle while mobiling.

Needless to say, this thing is tall. There is a monofilament line attached to the top of the antenna with loops at various places, that I pull and hook around a convenient place in the interior. 50 pound test is what saves this antenna from trees, branches, etc. Since people can't see the line, the setup - which as you can imagine gets some stares to begin with - eyes bug out when it appears to be moving all by itself. But I digress.

Anyhow, I pretty much assumed that there might be some small tuning differences on the lower frequencies, but I was just making sure that I wasn't running the road to perfidy with any hidden "gotchyas" - like if a stinger goes too far into a loading coil - one of those things that might not be completely intuitive until after the fact.

because we are not living in a free market driven economy. the
government regulations put a minimum wage requirement and taxes on
everyone so there is no way that bringing in more labor would reduce
the price of manufacturing so we could compete with china and other
cheap labor countries.

Really sounds like you are reinventing the old Swan mobile antennas. I
have an almost new in the box, motor driven unit that has the
switching mechanism just like you are thinking about. The motor in the
bottom unit has a dial-cord wound around it's shaft. The other end of
the coil loop goes over a pulley and a sliding contact is attached to
the dial-cord.

Is this what you are envisioning?

Hi Mike,

A rare confab of actual antenna design details. No controversy. No
wonder there are so few postings. Mike, on this cat walk of
fashionable posing, you are a buzz-kill.

How long are those tap wires? In other words, is this manual switch
sitting on your dashboard?

>There is also the matter of
>that tuning coil at the bottom of the antenna to ground, which varies
>between 8 turns of number 12 on a 1.5 inch diameter coil on 75/80

Why have a coil there at all?

>The antenna itself is semi-standard bugcatcher, a four foot bottom
>section, followed by the six inch coil, (standard GLA systems) followed
>by another roughly foot and a half section, then a 16 inch Capacity hat,
>then a spring and topped off with a 102 inch whip.

Uh-huh. So you have a "top" hat that is actually very close to the
center? A center hat as I might be wont to describe it?

I've often thought (and probably modeled at some point in the last 20
years) about putting such "top" hats at regular intervals along a
vertical radiator. Sort of like a bottle washing brush kind of
design.

>Taps at the present
>short out the remaining coil below themselves.

Back when we had more designers writing here, instead of Xerox junkies
and home-spun Platocrats, the discussion of shorted coils made them
apoplectic where those turns became huge losses. This is different
from the screwdriver approach which shields those turns.

>Anyhow, I pretty much assumed that there might be some small tuning
>differences on the lower frequencies,

Well, as I inferred, IFF you knew what frequency any unadorned (unchanged) original design was going to reside at; then I could well imagine it would shove that understanding under the bus. IFF, on the other hand, you have no idea (other than a general one of plus or minus one MHz) of where the initial state of tune was, then it probably wouldn't matter.

But of course you will (I'm looking forward to those stories) - otherwise you would have bought an antenna with a guarantee. In regard to this last I have to tailor a quote from one of my favorite authors, Walter Mosely:
"...you won't get to enjoy the honey,
if you worry the bees be stingin' you."

The initial plan is to have something perhaps located on the lower mast so that I can experiment with it. the final version will be eletrically or electronically switched, (most likely electrically) the switching taking place at the antenna - probably located on the lower mast.

>> There is also the matter of

> Why have a coil there at all?

It's sort of the butternut HF6V (and family) thing, I can tune the thing, but unless I place a Matching coil there, the minimum SWR might be around 2.5 to one or even higher, except where the antenna is becoming a more normal length. In the end, it's no doubt to compensate for the crazy low impedance on a short antenna.

>> The antenna itself is semi-standard bugcatcher, a four foot bottom

Yup. I had looked at placing it higher, but that ended up defeating my tie down idea, and those cap hats are kinda like wind dams - In the end I wanted it attached to some sturdy part of the antenna.

>> Taps at the present

I'm wondering where the issue comes from. As I look at it, the shorting
is making the bottom part of the mast slightly longer. I have to imagine
that not shorting it would be worse. Dunno, though.

I'll end up knowing, my tap system so far is a modified clip that has a
marked place on the coil. It works ver well, when very well is defined
as stays on and sends to power where I want it.

What got me started was last weekend, out late at night in just about
the most rural area in Pennsylvania, dragging out a stepstool to change
80 meter taps. New moon, and I forgot my flashlight. While the antenna
"works" pretty well for the genre, needing a stepstool is just not that
wonderful.

When I lived in an apartment temporarily a few years ago I had a
similar situation. The back of the apartment and my bedroom window
faced a wooded area so I strung up about 50 or 60 ft of wire using a
long piece of PVC pipe to push it up into the trees. I used it with my
MFJ tuner and enjoyed a lot of SWL time. Yes the tuner helped compared
to the antenna terminated in a banana plug and pushed into the
connector on the back of my IC 729. Take notes on how you set up the
tuner for various frequencies

Hi Mike,

That, too, was part of the raging debate. I have long forgotten the particulars, but I will hazard their argument. That is, in these highly reactive designs there are large potentials and high currents. With those circulating currents (the usual province of these considerations are in the tuner) AND the proximity of a shorted turn, you have a transformer relationship feeding the loss of the small diameter wire and/or the resistive short (rarely do switches offer optimal solutions in the face of truly enormous currents).

Screwdriver designs pre-empt this through the coil being nested inside of the conductive cylinder - no transformer action, or at least so goes the argument.

Reggie entered into these issues with his own observations about coil length, diameter, winding pitch, and placement to summarize his optimal design. You may want to look into that insofar as your base loading goes.

Good of you to post that Ian. I'm afraid I missed your lecture- one of several "clashes" where interesting lectures happened at the same time. It was almost a case of "toss a coin".

I hope you enjoyed the Convention, we (my XYL and myself) certainly did.

water flow and water waves are NOT good analogs for electromagnetic
waves. the only common part is that some part of the solution of
their equations includes a sine or cosine function.

:-) The bottom of the ocean going up (and down), i.e. earthquake, is
the major *cause* of Tsunami waves. Once set in motion, no further
movement of the bottom of the ocean is necessary. The energy in a
Tsunami wave extends all the way from the depth of the earthquake
source to the surface. Almost all of the water molecule movement in a
Tsunami wave is up and down. There is virtually no simple flow in a
Tsunami wave since the *energy* is traveling at hundreds of meters per
second. If it was "simple flow and not a wave" the energy in the wave
would be dissipated in accelerating the water molecules to a velocity
of hundreds of meters per second. Hint: Try making a spinning top out
of an unboiled egg.

Years ago I built a J antenna for 10m. I was actually pleasantly
surprised at how easily it tuned up compared to the 2m versions I had
buit. I checked for feedline radiation by checking for variarions in
VSWR while coupling a large mass(me) to the feedline near the feed
point. Little change was noted. Do the larger versions of this antenna
normally perform better(more predictably) or was this just a case of
dumb luck.

no, waves can transport energy without mass. photons have not rest
mass, only energy... look that up in your favorite wikipedia. sound
waves require mass, but don't have to transport it, just move it back
and forth around a point, thus they move energy without net movement
of mass.

ah, grabbed another non-sequitar term to add to your gibberish now?
for how long will everything be a soliton to you?

4415. Why do we short coil turns ?

Newsgroup: rec.radio.amateur.antenna
Date: 2010-10-17 11:42:57 UTC
From: Alejandro Lieber <alejandro@Use-Author-Supplied-Address.invalid>
Message-ID: <i9eng1trb1@tioat.net>
Source record: 7015

Since I built my first 80meter/40meter 6aq5 + 6DQ6 transmitter with pi
output in 1972, when I want to vary the inductance of a coil in a
tunner, or loading coil in an antenna, I just short circuit some turns.
I see that this is the usual practice everywhere.

My question is why do we not just leave the turns open circuited instead
of short circuiting them.

It appears to me that in the short circuited turns, a very big current
must be circulating, adding heat losses and lowering the Q of the circuit.

you are correct. and if the coil is on a core it can overheat the
core also. leaving them open also causes problems since it looks like
a transformer with an open circuit it can develop very high voltages
and flash over the band switch. The best method is to have separate
coils that are not coupled, but that of course gets more expensive and
larger. better amps have a combination, usually shorting turns on an
air core inductor for the high bands and then adding separate toroids
and capacitors for the lower bands.

an example of what can happen with shorted turns:

http://wiki.k1ttt.net/2008%20Maintenance%20and%20Upgrade%20Blog.ashx#hf2500

For a screwdriver antenna, the problem is solved by a conductive
sleeve over the outside of the shorted turns that keeps most of the RF
on the conductive sleeve instead of in the shorted turns of the coil.

that doesn't really 'solve' it, that just provides a single big
shorted turn instead of many turns.

Good Grief! The deeper the ocean, the faster the Tsunami wave travels.
The Tsunami wave slows to a crawl when it reaches land and indeed is
forced by the slope of the land to travel horizontally. Unfortunately
for your argument, I was talking about the speed of a Tsunami wave in
the open ocean which can be as fast as a 757 jet airplane. From:

http://www.enchantedlearning.com/subjects/tsunami/

"The Speed of a Tsunami: A tsunami can travel at well over 970 kph
(600 mph) in the open ocean - as fast as a jet flies. It can take only
a few hours for a tsunami to travel across an entire ocean. A regular
wave (generated by the wind) travels at up to about 90 km/hr."

http://www.infoplease.com/ipa/A0930274.html

"For example, at the deepest ocean depths the tsunami wave speed will
be as much as 800 km/h, about the same as that of a jet aircraft.
Since the average depth of the Pacific ocean is 4000 m (14,000 feet) ,
tsunami wave speed will average about 200 m/s or over 700 km/h (500
mph)."

Exactly how much horizontal movement can there be in the water
molecules when the Tsunami wave is moving at 800 km/h (200 m/sec)?

Maybe the single big shorted turn IS the solution? :-) When there are no actual shorted turns, i.e. all of the coil is exposed, does the bottom section of aluminum tubing become that same single big shorted turn? In any case, one very conductive and very wide shorted turn is a lot less lossy than a number of small shorted turns.

mass, only energy... look that up in your favorite wikipedia. sound
waves require mass, but don't have to transport it, just move it back
and forth around a point, thus they move energy without net movement
of mass.

So read the Wiki:
"For a pure wave motion in fluid dynamics, the Stokes drift velocity is the
average velocity when following a specific fluid parcel as it travels with
the fluid flow. For instance, a particle floating at the free surface of
water waves, experiences a net Stokes drift velocity in the direction of
wave propagation.
More generally, the Stokes drift velocity is the difference between the
average Lagrangian flow velocity of a fluid parcel, and the average Eulerian
flow velocity of the fluid at a fixed position. This nonlinear phenomenon is
named after George Gabriel Stokes, who derived expressions for this drift in
his 1847 study of water waves."

This nonlinear phenomenon is in each real wave. In texbooks are a paper
waves - for kids. They are linear and symmetric.

"just move it back and forth around a point" is a simplification necessary
in schools.

no, it becomes a very small diameter and long shorted turn... but yes, it is a shorted turn. you don't see as much effect because it is smaller in diameter so the self inductance is smaller and it only intercepts a fraction of the flux from the end of the coil. you get more of an effect if you place an air core coil with its end near the side or bottom of a metallic enclosure, the plate looks like a shorted coil and can have large circulating currents.

that is why they get away with it, the losses in the big fat thing are low enough that it causes less trouble than shorting turns with a switch or relays.

ah, but that requires fluid flow. electromagnetic waves do not require fluid flow or they could not travel at c. There may be some analogous phenomena in plasma where you can get non-linear effects but they would not propagate at c, they would be at some much smaller velocity.

Only fairly basic AC circuit theory is needed to analyse the effect of the shorted turns.

If you have a air cored solenoid inductor of n turns, and short m turns at one end, you can treat that as two independent inductors of n-m and m turns with some flux coupling factor k. The mutual inductance can be calculated, and a T equivalent of Ln Lm-n Rn Rm-n M elements constructed and solved. k of course depends on coil construction and n and m, a value can be determined by measurement of the reactance of the combination. (You might be surprised at how low k is.)

Essentially, when the power lost in the shorted turns is low (due to the combination of low k and low R), then the technique works fine.

We (hams) have some pretty inadequate word based explanations for some of these kind of things when there are simple quantitative solutions at hand.

An example is the traditional explanation of link coupling ratios. See http://vk1od.net/tx/concept/lctr.htm for a quantitative explanation using the same techniques as suggested above.

BTW, the solenoid inside an aluminium tube is a case of an inductor surrounded by a single shorted turn... but if R in that turn is very low, then little heat is generated in the tube.

We also sometimes use a movable shorted turn to adjust an inductor... a brass or preferably silver plated brass slug was often used in VHF / UHF tuned circuits.

Owen

Already answered earlier in this thread. For HF frequencies, the
horizontal movement of the electrons is minuscule and they can be
considered to be oscillating in place. It is the photons that move at
the speed of light.

To give a mental arithmetic example...

Assuming ideal inductors for the moment...

Suppose you had an air cored inductor, that when you measure the
inductance of the first half of the inductor (other terminal open) you
get 10ï¿½H. You now measure the whole inductor and get 30ï¿½H. We can
calculate that M=5ï¿½H.

Now forming a T equivalent of the inductor with one half shorted,
L=10+5+(5//(10+5))=18.75ï¿½H. Notably, the current in the s/c is
3.75/15=25% of the current in the other section, so losses are about 6%
of that in the other section... not usually a big issue.

That is, if I got the maths right on the fly!

Now, real inductors have some distributed capacitance which changes this
as you approach the inductor's self resonance frequency.

This works ok because mutual inductance is lowish. Increase k by
introducing a magnetic core material for instance, and the situation
changes.

You might see the technique applied to powdered iron core inductors. Not
necessarily a good idea, but it 'works' for some because they are low
permeability powders and flux leakage is high (ie k is not nearly 1).

Owen

EM waves are the torsional vibrations in a solid dielectric. In solids are
the strains. Tiny flows.

> There may be some
analogous phenomena in plasma where you can get non-linear effects but
they would not propagate at c, they would be at some much smaller
velocity.

The vector calculus describe only movements.
Ancient people describesd the planet movements. But the planet were
described more later.

The same is with the radio waves. They are still not described physically.
In the description must be words electrons and voltage.

considered to be oscillating in place.

Waves are described in the two method: " More generally, the Stokes drift
velocity is the difference between the
average Lagrangian flow velocity of a fluid parcel, and the average
Eulerian flow velocity of the fluid at a fixed position. This nonlinear
phenomenon is named after George Gabriel Stokes, who derived expressions
for this drift in his 1847 study of water waves."

> It is the photons that move at the speed of light.

Photons are the math joke.
Electric waves in a medium made of electrons move at the speed of light.

But, isn't that conductive sleeve itself a shorted turn? It's
conductive, coaxial with the rest of the inductor above the sleeve, so
the magnetic field certainly passes through it.

I think the real answer is that everything is a tradeoff.

One could look at one of the standard equations for solenoid inductance
(e.g. Wheeler's) and get a feel for it. The ideal fully coupled multi
turn solenoid would have inductance proportional to Nturn^2.

Wheeler (for inches) is: L (uH) = r^2 * n^2 / (9 * r + 10 * l)
so there's the n^2 term on the top, but there's also the 10*length term
on the bottom.
For 2" diameter, 5 turns/inch, I calculated Wheeler L and for comparison
Length^2/6 (so that the number would be comparable at a length of around
12")

length turns Wheeler L uH/inch Length^2
2 10 3.45 1.7241 0.67
4 20 8.16 2.0408 2.67
6 30 13.04 2.1739 6.00
8 40 17.98 2.2472 10.67
10 50 22.94 2.2936 16.67
12 60 27.91 2.3256 24.00

14 70 32.89 2.3490 32.67
16 80 37.87 2.3669 42.67
18 90 42.86 2.3810 54.00
20 100 47.85 2.3923 66.67
22 110 52.84 2.4017 80.67
24 120 57.83 2.4096 96.00
26 130 62.83 2.4164 112.67
28 140 67.82 2.4221 130.67
30 150 72.82 2.4272 150.00

You can see that for this kind of coil, the coupling from turn to turn must be pretty low.. The L looks closer to a linear function of length than to the square of turns. If it were perfectly linear, it would be as if there is NO turn to turn coupling, and is just a series combination of single turn uncoupled inductors. If you look at the uH/inch column you can see that once you get into the 10 inches long and up range, it *is* almost completely linear.

Not really... that used to be an explanation, because for conveniently sized coils, the length of the wire on the secondary is pretty close to a 1/4 free space wavelength at the resonant frequency. However, you can build tesla coils that deviate pretty strongly from that, and they still work well, indicating that the 1/4wavelength (or slow wave transmission line) model isn't all that hot.

The current/voltage distribution along the secondary is pretty close to linear, especially if you have a decent sized topload.

It's resonant, but not 1/4 wavelength. You can model a tesla coil's behavior to within about 5% using a simple lumped LC model. The secondary is a lumped L and the self C of the inductor plus the C of the "topload".

There's some pretty rigorous analysis out there of tesla coils these days. Paul Nicholson's analysis is probably one of the best
http://abelian.org/tssp/

and has been confirmed by measurement.

Antonio C.M. de Queiroz has some elegant analytic models of coupled resonators which adequately describe most tesla coil configurations (including magnifiers) and more to the point, his analysis predicted some new ways to operate a coil, which were proven in practice by some experimenters. (that's sort of the proof in the pudding of theory.. it predicts some behavior that hasn't been seen before, and when you look for it, you find it)
http://www.coe.ufrj.br/~acmq/tesla/magnifier.html

There are some very nice finite element codes out there for Tesla coils, as well. JavaTC is based on one of them

Light is not coherent. It is "produced" in the packets (photons). But the
radio waves and the radiation from the "free electron laser" are coherent.
When the photons start and when finish?

@viwinnwfe02.internal.bigpond.com:

Well, I didn't get the maths right, there was a sign error in the formula
below. Here is what it should have read.

Suppose you had an air cored inductor, that when you measure the
inductance of the first half of the inductor (other terminal open) you
get 10µH. You now measure the whole inductor and get 30µH. We can
calculate that M=5µH.

Now forming a T equivalent of the inductor with one half shorted,
L=10-5+(5//(10-5))=7.5µH. Notably, the current in the s/c is
50% of the current in the other section, so losses are about 25%
of that in the other section... not usually a big issue.

Of course, the situation depends on the tapping point, and is much worse
when you short just one turn... but we don't usually do that. The example
has a fairly high coupling factor k (for an air cored coil), and losses
are lower for lower k.

I am working on a note that expands on this.

Owen

How can a model that presumes faster than light speeds yield a valid outcome? Drs. Corum seem to disagree with you. Here's what I have been quoting:

http://hamwaves.com/antennas/inductance/corum.pdf

Drs. Corum seem to debunk the lumped LC model. They also once had some class notes titled: "Tesla Coils and the Failure of Lumped-Element Circuit Theory", but I can't locate it on the web.

For an average air-core coil, the delay through the coil seems to be
in the ballpark of half of the coil wire stretched into a straight
line, i.e. the VF of the coil is about double what is the VF of the
straight wire used to wind the coil. The turn to turn coupling exists
but turn to far away turn coupling is very low.

This seems to be the most accurate inductance calculator that I have
seen and includes the characteristic impedance and axial propagation
factor.

one could simply slit the tube (and finger stock at top). Consider that the lower tube is serving two purposes: mechanical support and a movable contact on the inductor.

Changed the topic.. and really, this isn't r.r.a.a territory any more..
Feel free to send me an email directly.

This has been thrashed through pretty thoroughly on the Tesla Coil
Mailing List (TCML, http://www.pupman.com/) and I'd refer interested
parties to the list archives, or, to the works by Paul Nicholson.

I've had some nice discussions with Corum the younger, but, their model
makes life harder than it needs to be. Occam and all that.

At TC resonant frequencies (100kHz), the "light time delay" from top to
bottom of a 3 foot high coil is pretty small. I don't know about faster
than light, but at 100kHz, for an object that's a meter or two in size,
assuming simultaneity isn't a big stretch.

(for the propagation of the spark, though, and the current flow in the
top load, yes, the speed of light matters, and in fact, the speed at
which the charge can get off the top load and into the spark channel is
probably one of the bigger factors affecting maximum spark length.)

People have also put current and voltage probes at the top and bottom of
the secondary coil (with fiber optic connections etc.).

Getting to the "transmission line" or "slow wave structure" aspects..

You've got an inductor with a lot of stray distributed capacitance.
Indeed, that's exactly what a transmission line can be modeled as
(distributed series L and shunt C). And with an arbitrarily complex
nonlinear distribution of L and C, you can make a transmission line that
acts like a lumped L and C of the appropriate values.

So, the question really is, do you want the simple model or the complex one. If the goal is to design better tesla coils, and the simple model gets you to fractions of a percent in terms of agreement between experiment and theory, why use the more complex model. It doesn't lead to any better understanding of how it works, either.

Now, if you want to talk about modeling the spark channel as a time varying lossy transmission line, that's something more interesting, and it DOES have value in terms of understanding/predicting the behavior. For that, I'd point readers to "Spark Discharge" by Bazelyan and Raizer, which is one of the best works in the field, and a fascinating read (and, as well, they have that cool 150 meter+ spark picture from a really, really big Marx generator, 1.2 MJ or more, in Siberia)

One thing I'm wondering. In your world, how does the energy jump from
electron to electron? And try to make some sort of sense for once. Please.

4450. Swan antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2010-10-19 01:45:55 UTC
From: "J. Mc Laughlin" <jcm@power-net.net>
Message-ID: <4uGdnREamIrWZSHRnZ2dnUVZ_j2dnZ2d@bright.net>
Source record: 7050

An EBAY picture of a Swan antenna c. 1960s was part of a thread. The patent number seen in the picture was below resolution. A search found what I think is the patent. It is only 7 pages long. U.S. Patent 2,961,657 Nov. 22, 1960.
Here are the classification numbers: 343/714 ; 336/150; 343/722; 343/745; 343/900; 343/906; 455/121; 455/92

Class 343 is the class for antennas.

You can go to this URL and enter patent number:
http://patft.uspto.gov/netahtml/PTO/srchnum.htm

Another couple questions. Should be easy answers for you.

Since your model supposes that the "plasma" carries the signal, what
does the model predict as the radiation resistance of a dipole in free
space?

Given your model, which you have spoken about at some length but no
depth, why wouldn't your predicted radiation resistance change with
plasma density, contrary to all measurements ever made?

Photons and incoherence are the same. "In 1900, Max Planck was working on
black-body radiation and suggested that the energy in electromagnetic waves
could only be released in "packets" of energy".

In a black body is many dipoles which work with brakes. In radio a dipole
(or monopole) works continously.

They have the kinetic energy. "the energy jump from electron to electron"
by collisions.

It is a full analogy with the acoustic waves. Molecules are the medium for
acoustic and free electrpns for the electric waves.

It is not my model but Tesla's. Probably he was spoken deeper.
You try to marry Heaviside with Tesla. TEM are not longitudinal.
Longitudinal waves have analogy with acoustic waves.

These two concepts seem to be contradictory. Some simple 1/4WL Tesla coils are obviously close to 90 degrees long and limited by the speed of light. The traveling waves cannot travel faster than the axial propagation factor, whatever that value might be. For those simple Tesla coils, there is an electrical ~1/4WL between the feedpoint and the spark. Simultaneity is impossible in the real world.

Stalin had the science writers purge their texts of those qualities that you miss and that we enjoy here in the west (they were condemned as bourgeois inspired perversions with counter-revolution tendencies). Hence you find decrepit pensioners sneering at elitist propaganda (western science) that dismisses the party-approved water models of RF transmission. In the historical perspective, we have to remember this state inspired instruction was learned in an era of RF transmission jammers located in every neighborhood so that trying to hear the VOA or the BBC made things sound like you were listening through the breakers of the surf. Hence the "experience" of the water model was very pervasive and arguing its falsity comes up against the resistance of the old guard.

Long, long ago, I possessed a few copies of some of Teslas' original notes, thoughts, sayings, etc. condensed in a thin little book. I can remember reading it and contemplating what he was thinking/saying. I got a distinct feeling Tesla seen his "magnifying transmitters" and the "receivers" as, on resonance, being connected together by an "invisible wire" ... I still think I may have missed a lot of what he knew/discerned/guessed/thought/etc. He was nothing short of utterly amazing ... possibly "insane like a fox."

BTW. I Square Danced from the time I was ~17 to 26, some of the best times I ever had. Got into exhibition dancing in front of large groups, just for fun ... times were a lot simpler/better then ...

Regards,
JS

Always are the two descriptions. Physical (dynamic) and geometric (kinetic).

"Geometric algebra in the sense used in this article was not developed,
however, until 1844, when it was used in a systematic way to describe the
geometrical properties and transformations of a space
"Nevertheless, another revolutionary development of the 19th-century would
completely overshadow the geometric algebras: that of vector analysis,
developed independently by Josiah Willard Gibbs and Oliver Heaviside. Vector
analysis was motivated by James Clerk Maxwell's studies of electromagnetism,
" From: http://en.wikipedia.org/wiki/Geometric_algebra
>

Tesla's longitudinal radio waves are also described.

For us is enough to know that the transversal are rotational. The geometric
desription of the rotational oscillations is very impressive. It must be in

the school program.

Stokes drift is also impressive. Do you know that the ink printer use it?

So to return to my real world example, an air core solenoid used as a tuning coil for a bugcatcher antenna, would I be wanting to short the unused portions of the coil, or leave them unshorted?

Seems that unshorted would be bad.

Indeed, but some shorted turns intercept more flux than others.
Hopefully the field in the passenger seat is small enough that the power
dissipated in one's spouse's ring is fairly low.

Given the relatively few turns on a typical bugcatcher, and the low coupling of flux, the voltage rise would be negligible, and the fact that you're not having a high voltage across the coil in the first place (compared to turn spacing), I don't think it's an issue to leave the end free.

Practical experience: On most tesla coils, the primary is a 10-20 turn coil with turn to turn spacing of 1/4" to 1/2" or so and runs at a peak voltage around 20kV. One adjusts the tapping point to adjust the primary L to bring the system into resonance, and it usually winds up being tapped about 70% of the way into the coil. Almost never do you get arcing/corona from the free end of the coil, which is potentially at as much as twice the voltage, and if it were in free space, you'd start to see corona from the relatively small radius of curvature.

Movements in 2D are described on the imaginary plane, in 3D by vector
calculus, in more D by tensors.
You need not know that to analise the radio waves.
But you should know that no pure transversal waves. Always are the two
components.
Heaviside did not know that.

The stub match can be used at hf too.

Using a stub, the balun can be integrated into it as well. A couple
of photos of my homebrew 20-meter monoband Yagi demonstrate.

http://k6mhe.com/n7ws/YagiFeed-1a.jpg

http://k6mhe.com/n7ws/YagiFeed-2a.jpg

Note: the antenna is sort of "upside down" as it's on a fold-over
tower that was folded over at the time

> Seems that unshorted would be bad.

I wrote some notes based on a simple model of an air cored single layer solenoid, they are at
http://www.vk1od.net/tx/concept/TappedCoil/index.htm .

The model suggests that shorting the unused turns is a poorer solution when the flux coupling factor is relatively high, and a very small number of turns are shorted. Poorer both because of loss and the granularity of L adjustment.

In that situation, the voltage induced in open unused turns is not very high, whereas it can be extreme in cases where most of the turns are unused.

So, a combination of methods may be optimimum, depending on the flux coupling factor, voltage withstand, granularity of variation of L, etc.

The Old Guard is often found trying to commemorate the past in
relation to their old heroes:
"In Paris, on August 28, 1844, at the Cafï¿½ de la Rï¿½gence on the Place
du Palais he met Friedrich Engels, who would become his most important
friend and life-long companion. Engels had met Marx only once before
(and briefly) at the office of the Rheinische Zeitung in 1842;[28] he
went to Paris to show Marx his recently published book, The Condition
of the Working Class in England in 1844.[29] This book convinced Marx
that the working class would be the agent and instrument of the final
revolution in history."

The faded political trash that is now used as decoupage for today's
arguments is carnival in spirit but is as nutritionally substantial as
cotton candy.

Something sort of like that,- my version would have a box underneath the
loading coill where the wires would end up.

As you know I am collecting the evidences. Could you tell me something about
the cristal radio?
There is the diode. The electrons flow in the one direction. The questions
are:

1. Electron must flow from the antenna to the ground,
2. In the opposite direction.
3. Radio works in the both arrangement.

It would be easy to collect the information from the own laboratory. But
asking is the substantial.

Nope, RF electrons don't actually flow. They essentially vibrate in place. "For a copper wire of radius 1 mm carrying a steady current of 10 amps, the DC drift velocity is only about 0.24 nanometer per microsecond." At 10 MHz, the electrons would vibrate back and forth at about 0.01 nanometer per 0.1 microsecond. Consider how large 0.01 nanometer really is so for all practical purposes, electrons don't flow at all at HF frequencies. Electrons at HF are just a bucket brigade for the photons that deliver the RF energy to the diode detector. Unless a circuit is at DC steady-state, photons are involved, i.e. RF involves photons which constitute the RF fields and RF waves.

After taking a good look at the loading coil, its apparent that there
isn't much choice. The bottom of the coil is attached to the lower mast,
and a four pronged plate that the tap wire is attached to at the same
junction. So unless no tap is used, some portion will be shorted/
bypassed or the like.

And given that GLA systems is no longer in business, my loading coil
just got a lot more valuable, so I'll have to experiment on a new coil.
I have the Acrylic top and bottom pieces, next will be getting the rods
and make the wire cheannels.

Kinda my original question.

Intuition tells me that ideally - in order of preference:

1. the entire unused portion of the coil should just disappear.

2. A shorting sleeve that renders the unused portion of that loading coil as a fatter part of the mast.

3. What I have now, a #12 wire from the top of the bottom part of the mast to the spot that I tuned the antenna. The bottom of the coil is attached to the same point on the bottom mast.

1. is impossible without having separate replaceable tuning coils. Crazy inconvenient.

2. This would be the world's fattest screwdriver antenna.

3. This becomes the question? Is this worth worrying about? And testing would be interesting for each frequency to determine which ones benefit from shorted/non shorted operation.

Which now leads me to ask, what would be a good way to set up such an experiment? I guess if follows on that what exactly is the phenomenon that I would be witnessing? A transformer effect in unshorted condition certainly would be a problem even for my transmitting equipment?

I can not debate your particular area other than to point what I have
in actuality.
By removing all reactance especially the magnetic field the current
flow removed itself from the material and travels on the surface.
This is not unusual as superconductors drop to zero resistance when
the magnetic field is canceled or removed. There are only two
resistances in radiation and if no skin depth is then generated then
the material and its resistance is removed from Maxwell's equations
Now one can question my understanding as to what is happening but the
fact is my antenna
swr does not go above 3:1 no matter what band I am on! Yes, by not
understanding what is really happening it would be easy to say "dummy
load " but that is not the real answer.
So I would ask all what exactly is impossible

about the sequence of event that I describe while adding that computer
programs confirm it?
By the way the antenna is sitting om the grass
as height does not affect dish antennas!

Yes, but even better, a new coil optimised for the band. Not an original
thought though!

>
> 2. A shorting sleeve that renders the unused portion of that loading
> coil as a fatter part of the mast.

Mike, some thoughts.

A word explanation of what my simple model draws out quantitatively for
an ideal coil (meaning insignificant distributed capacitance)...

Just one turn shorted / open...

If you short just one turn at the end of the coil, a current is induced
in the shorted turn. The current depends on the flux coupling factor k
and the number of turns in the rest of the coil. The loss depends on the
current squared and resistance... so whilst the current squared might be
high, resistance would be relatively low. Nevertheless, if k is high,
then the current induced in that shorted turn will increase total loss
significantly. The effect of a large current in the shorted turn is to
reduce the inductance of the combination, the higher the current (high
k), the greater the reduction in inductance.

If on the other hand, that one turn was left open a voltage is induced in the open turn. The voltage depends on k and the number of turns in the rest of the coil.

More turns shorted / open...

If more turns are shorted, the induced current is lower, and R is higher, the net effect is that additional loss is reduced. Inductance is reduced, but at a slower rate than intially.

If more turns are left open, the voltage induced in the unused turns increases and could be many times the voltage developed across the used turns. A first approximation is k times the turns ratio times voltage developed across the used turns.

Shorting each of several adjacent turns...

This approach assures the highest circulating current in the shorted turns, assuring the worst loss at all tappings.

Screwdrivers...

The approach taken in some screwdrivers uses a very low resistance shorted turn (the tube) to make contact at the tapping point, and it protects the unused coil turns (now inside the tube) from flux. Done properly, that might well be a fairly good solution... I haven't tried to measure it.

k...

Avoiding high k provides finer granularity of inductance adjustment and lower loss when few turns are shorted... but of course lower k means a physically larger coil for the same inductance, and potentially higher R which increases loss.

Owen

But in that situation, the voltage across the unshorted turns is likely
to be low, because you've got low reactance, right? So the net effect is
small.

Hi Jim,

It depends what you take as a reference. A rough estimate of the voltage across the unused turns is the turns ratio (unused /used) time the flux coupling factor, which in practical applications is likely to be in the range 0.2 to 0.5.

If the application was a valve amp pi coupler, the voltage impressed across the used turns could be a couple of thousand volts, and on a 10m tap, the voltage across the unused turns could easily be 5 to 10 times that.

In the case of a loading coil for a multiband whip, the current in the used turns is probably similar from band to band, but the used turns are lower for higher bands and so the flux cutting the unused turns is lower, but there are more unused turns. In this application, insulation problems are probably less severe than the PA with a bandswitch.

To my mind, the interesting thing is why shorting some turns is 'ok', and then to understand that doesn't make it 'ok' in all scenarios. For instance, someone taking a valve amp pi coupler and implementing it on a single powdered iron core changes the situation significantly.

Re the Tee circuit, yes, but it takes a while to draw it up... not nearly as quick as grinding a few numbers and creating a graph! I have a backlog of hand drawing scanned into articles to redraw already.

Thank you very much for the explanation.

Another interesting and very practical graph would be: for a 20 turn,
50mm diameter and various winding pitches coil, how much additional
energy loss, 1, 5, 10, 20, 30, 40 additional short circuited turns add.

Wiki is more usefull than you:
http://scitoys.com/scitoys/scitoys/radio/homemade_radio.html
" Power from radio waves -- hooking up a meter to measure the voltage and
current "

"If you have a good antenna, or a strong radio station nearby, the ammeter
might read more than 50 microamps. If you have a short antenna, you might
get only 5 microamps and still be able to hear the station clearly in the
headphones. I put up a 200 foot antenna between two trees over my house, and
tuned to a 50,000 watt station about 30 miles away, and now I get 175
microamps of current through my meter."

Hello Alejandro,

I think the graphs in the article demonstrate that there is a simple analytical solution, giving the appropriate parameters.

There are issues about the applicability of the model to the real world, but the model does show trends about what is desirable and undesirable practice. Wheeler's formula for inductance has its shortcomings (Wheeler's formula doesn't take into account wire diameter for instance), but it is (IMHO) sufficiently accurate to expose some of the 'interesting' effects that prompted your initial question.

The model is based on basic electricity and magnetism, stuff that isn't so appeallng to new age hams.

Owen

> programs confirm it?

You want the Bush or the Obama explanation?

Lets ask both.. Hey Gee Dub, what do you think?

"Son, your misapplication of the modeling programs
have led you astray. Number one, you can't polish a
turd into a diamond. Believe me, I've already tried it
out at the Crawford ranch. Didn't pan out...
Number two, the modeling programs are not coded to
deal with turd polishing. So any results obtained from
misapplying an antenna modeling program to simulate
the performance of a polished turd is bound to end in
frustration and gross error."

Hey Barry, what's your angle?

"I think we should give him a $500.000.00 grant!"

I guess it was a split decision.. :/

> By the way the antenna is sitting om the grass

I prefer Wiki:
"The voltmeter in the same radio reads 125 millivolts. Since watts (the
measure of how much power we have) is the voltage multiplied by the amperes,
we have 0.000175 times 0.125, or 0.0000218 watts, or about 22 microwatts.
The station is putting out 50 killowatts, and we are receiving one ten
billionth of that power, yet we can hear it across the room."

Could you help? The simplest radio:
" Tape the other diode wire to a cold water faucet. This makes a good
connection to the ground, and is thus called a 'ground' connection.

Hold the remaining free bare wire of the earphone in your hand. This
makes your body into the antenna for the radio. Put the earphone in your
ear. If you are close to a strong AM radio station, you will be able to hear
that station faintly in the earphone. You may hear more than one station at
once. "

The diode has the two ends. Which one should be tapped to a cold water
faucet?

well, of course, once you put a diode in the circuit you are forcing
flow in only one direction. but try this, turn the diode around so it
only allows electron flow FROM the ground... and you will still hear
the station. so now how do electrons flowing from the remote antenna

through the air get to ground through your diode??

Stephen-

How high is high? Most modern radios can tolerate SWR up to 3:1.

On a specific band, is SWR high across the entire band? I understand the Buddipole is fairly critical, especially on the lower HF bands. It may need to be adjusted for the part of the band where you want to operate.

With the same power?

> so now how do electrons flowing from the remote antenna
through the air get to ground through your diode??

You forget about chassis. In the opposite setup the wire is the antenna and
your body is the chassis.

Are you rich enough to check the simplest radio?
Is the same power in the both arrangement?

The fog of ingrained stereotypes lives on long after the Soviet
Information Bureau published "Falsifiers of History." Stalin
personally edited the book, rewriting entire chapters by hand (how
well we experience this here, daily). The book claimed, for instance,
that American bankers and industrialists (are you rich enough?)
provided capital for the growth of German war industries.

:) Nicely put.

But the moron either won't get it or will deny it anyway. Matters little.

But we all know that there are positrons. So maybe he's right after all.

After a few milliseconds contemplation I've decided to go with not right.

Yes pretty much the same on all bands I think I might have solved my
problem the transceiver was not grounded sufficientally and when I did
this the swr came down on all bands expecting part of 40 is it correct
to say that swr is affected by station grounding ?

Ideally, the coax would carry negligible common mode current and you
would not notice such an interaction.

The Buddipole should be used with an effective balun. My preference would
be a current balun with a high choking impedance, but IIRC that is not
what Buddipole recommend.

Let the coax fall to the ground vertically, and route it away from the
antenna at right angles to minimise coupling.

VSWR will be poor on the lower bands (80, 40) if you do not have the
variable ratio balun, and set it appropriately.

You are really shy on details (eg we have as good as begged you to
quantify 'high'), so you get brief answers. Describing the problem well
to yourself is the first step in resolving it.

My only question is why does my crystal radio work without a ground
connection? Yes the radio does work better with a ground but that does
not negate the fact it works without a ground. And yes the radio works
with the ground and antenna connections reversed. The diode is a piece
of galena.

Source record: 6858

I have read that the presently available 300 ohm ladder line is
unsuitable to use at some amateur radio frequencies because of it's
construction and the losses caused by skin effect in the copper coated
steel construction. I have been using a Terminated Folded Dipole in a
flat top configuration as my HF antenna at home. Having recently
acquired an Icom AH-4 Antenna Coupler I am considering converting it
to a simple folded dipole, feeding it with 300 ohm ladder line to
match it's nominal impedance from the coupler. I know your sure that
there is a question in here someplace so is there better quality 300
ohm window line available that is entirely stranded copper in it's
construction?

Hi Tom,

You really have to question your judgment of the source of what you
are reading. The rationale of losses caused by "skin effect", and for
the very reason of it being copper is a perversion.

> I have been using a Terminated Folded Dipole in a
>flat top configuration as my HF antenna at home.

Revisiting this issue of line loss (however it was derived) in the
face of the loss in the terminating resistor of your antenna has got
your expectations inverted. Consider line loss in the tenths of dB to
1dB and the antenna loss easily double that worst figure (if not
triple or quadruple).

>Having recently
>acquired an Icom AH-4 Antenna Coupler I am considering converting it
>to a simple folded dipole,

Folding it adds no virtue.

> feeding it with 300 ohm ladder line to
>match it's nominal impedance from the coupler.

If it has a nominal 300 Ohm Z, then use a conventional BalUn and coax
solution.

However, methinks you are going to treat this antenna as Z=300 at all
frequencies. No way.

Tom, if you made a line of the dimensions of Wireman's 300 ohm line out of HT steel, you would be looking at matched line loss at 80m in the range 30 to 40dB / 100m, depending on the permeability of the steel wire.

If you made it out of copper, you would be looking at around 0.5dB.

The thing is that copper clad steel is somewhere in that range. If the cladding is more than say, three skin depths in thickness, loss will be almost identical to copper.Skin depth in copper is 35 microns, three times that is 100 microns amongst friends.

The strands of 19 strand #18 are 200 microns in diameter.

I have no idea what the copper thickness is, but I suspect it is less than 100 microns (as they would be pure copper in that case).

As Richard suggests, be perverse, ask the Wireman if he has measured loss data for the line at 3.5MHz, not extrapolated data from higher frequency measurements, but measured data.

I am not picking on the Wireman, Richard mentioned them, but I think the same issue exists for all suppliers.

The only nominally 300 ohm line that is pure copper that I have seen is TV ribbon, but that is probably not as good as you seek.

Think about the Wireman's 551 which is a single core CCS. If it is 30% CCS, the cladding depth is about 7% IIRC, and that would make it 70 microns... might just scrape in with near copper performance on 80m.

The Rule of Thumb usually used is 2.5 to 3 times the skin depth gives near copper performance.

Owen

For me, it's not the wire that is a problem. It's rain..
When dry, most all the 300 ohm lines are going to
be fairly low loss. Even with the cheap wire.
But get the line good and wet, and it all goes out the
window. For this reason, I would prefer a windowed
ladder type line for this, rather than 300 ohm.
It's less effected by rain.
Most ladder type lines will be in the 450 ohm range,
but that would vary with spacing of the conductors.
But that is not critical in your case.. 300, 450, 600
ohms, doesn't really matter too much..

Tom, what length of feed line are considering? How do you intend to
install it and support it from your shack to the antenna?

I have tried both 300 ohm TV type twin lead and ladder line. Both are
quickly affected by rain and snow. But more importantly is the wind
whipping the feed line and breaking it somewhere. About once per 6
month period I had to pull the whole antenna down and either replace
the feed line or find the break and repair it.

If you are able to secure the feed line with insulators every 10 feet
or so, the wind damage should be minimal.

A couple of years ago I made my own 600 ohm open wire feed line and
the wind is no longer a problem. The wind resistance is very low and
weather is only a problem when ice collects on the feed line.

IF you are interested, the 600 ohm feed line is #14 copper with
plastic rod insulators every 10 feet. The length from shack to antenna
is about 125 feet. Two poles support the feed line on its way and the
shack end is attached to a rope and pulley so I can adjust the
tension, or let the end down for maintenance.

Just some thoughts for you. Good luck, and don't be afraid to try
different schemes.

We all know that for an open-wire feedline, Zo = 276 log 2S/d, where S= the center-to-center distance between the two conductors, and d= the outer diameter of each conductor.

As far as I know, this formula applies to single-core wires. Is there any significant difference to Zo where multi-strand wire is used instead? I'm thinking of how the RF skin effect might affect things. Or is it simply a question of treating the overall diameter of all the strands as one solid conductor?

Further, if the multi-strand wire is plastic coated, what effect does that have on Zo?

300 ohm line is probably not the best choice if you want to use non-coaxial feedline. Much better is real ladder line or window line.

And there are some serious misconceptions about window line too, so you hav eto be careful of what you read.

Wes Stewart, N7WS wrote what is commonly cited as ladder line's fatal flaw:

http://users.triconet.org/wesandlinda/ladder_line.pdf

I suggest that you read it.

But the study in itself suffers from a fatal flaw. And it is actually demonstrated in the article.

Stewart had difficulties in getting his ladder line completely wet. In fact, the water created antibubbles on the surface of the line, and ran off.

Well now, how do we fix this? We apply wetting agent to the line, this will cause the water to wet the entire surface, then measure the loss.

Anyone see the problem here? Last time I checked, there is no wetting agent in rain. This is testing of artificially wetted window line, nothing more, nothing less.

I have ladder line that has been up for 10 years now, and water still beads up on it like it did when it was new. I'll not even add that it is vertical, so there won't be as much water hitting it as when it comes form a spray bottle - oh wait, I did mention it.....

The characteristics of polyethelene which is used to cover window line in fact make it very difficult to be wetted. One might be able to enforce wetting by sandblasting the line to roughen the surface, or oh yeah, apply wetting agent.

That however makes the results of the experiment of equal value to modifying coax in a detrimental way, then measuring some aspect, and saying "all coax is like this". And why would ya do it anyway?

There are reasons to use ladder or window line, and there are reasons to use coax. For example, at our club mountaintop station, we use copperweld for the dipoles, properly hung on towers. There is a shrt run of normal premium coax, just enough to lower the antennas for maintence if needed, but the coax is switched to hardline coax for most of the run

into the shack. This is a good setup if you have lots of space, a goodly number of towers, and monoband (or at least fan) antennas.

Now for the home QTH, I have some limited space, around a 100 feet. yet I still want multi-band operation. So I'm looking at more limited choices.

Monoband dipoles are pretty much out of the question. Loaded multiband dipoles? For all the ham bands? Maybe not so good. Fan dipoles? a pain, and I'd have to start supporting the antenna on a messenger line.

So that ladder line or window line fed doublet is looking pretty darn good about now. Rain or shine.

> that have on Zo?

Assuming you mean bare wires twisted and then served with insulation...

Dielectric with rel permitivitty >1 will reduce Zo.

Have a play with TWLLC at http://www.vk1od.net/calc/tl/twllc.htm .

An effective way to estimate the effective permittivity is to measure the
velocity factor of a sample of line, and use permittivity=vf^-2.

"Antibubbles?"

>Well now, how do we fix this?

That the line was resistant to becoming "completely wet" would seem to
be a boon, not a problem, for its application.

>We apply wetting agent to the line, this
>will cause the water to wet the entire surface, then measure the loss.
>
>Anyone see the problem here?

Most wetting agents are detergents (in fact the whole point of using a
detergent is for complete wetting).

Sources are obscured through other applications, but glimmers of
evidence suggest that adding a wetting agent will quadruple the
conductivity of water.

>Last time I checked, there is no wetting
>agent in rain. This is testing of artificially wetted window line,
>nothing more, nothing less.

If adding a wetting agent is called for - in spite of its absence in
rain (for now until the new political alignment shitcans EPA) - it
will undoubtedly render the line as less than useful as would be
expected in either a wet or dry environment.

How did we get here?

It looks like I am going to have the resources to install a second antenna tower. I never thought it would work out this way so I have not planned it as I put other things in place.

The question is: How close is too close?

I know more separation is better and I doubt I can predict the future well enough to model expected configurations.

The first in place is the existing crank up mast with power winches that allow me to lay the whole works down for maintenance. HF tri band in place at about 55 feet.

About 50 feet north of that tower is my field of 36 radials where I currently have a 40 meter self supporting vertical. I would really like to not compromise the radials or the operation of whatever vertical I choose.

I am thinking of putting the "new" tower about 20 feet West of the vertical & radial field. The plan calls for 4 sticks of Rohn 25 on a tilt plate with a utility pole doing the stabilizing. Winches as required.

That is a little more co ax than I would like, but my real concern is whether this will be a major hit for the vertical and other antennas.

I would appreciate any thoughts and especially experience.

I have an ICOM 802 SSB and have set up my backstay on my sailboat as the antenna. My boat came with a Furuno weatherfax (208A) which I have never used. We can't find an antenna for it on the boat. Can I connect the weather fax to the backstay antenna and share it with the SSB ? If so do I need a switch to toggle to the device that is in use or can they compatibly share the one antenna.

Please forgive me if this is a stupid question....just learning...only have my Technician Ham license so far.

thanks for any help you can offer -

Hi John,

Consider the spacing of elements in an array (any, even vertical
arrays that are installed for directional AM stations). The
dimensions there are in the tenths (or less) of wavelengths and
couplings are very strong. You propose a second structure that is
still quite near (about .15 wave) on the basis of this simple metric
alone.

What it does is another matter. It will certainly disturb the
radiator's loading. It will certainly absorb signal. It will
certainly re-radiate that same signal. It will certainly introduce a
phase shift that combines with the original signal. The combination
can either produce a lobe or a null OR it may be unproductive in the
practical sense (all certainties go by the wayside).

One might pause and reflect that the new tower could easily (this is a
hail mary pass) serve as your 40M radiator. Why have two vertical
structures (ignoring that we will actually be talking about the
installation of a THIRD vertical structure if we include the south
tower)?

I have used for the past three years a 40M vertical and and 80M loop.
I use the 40M vertical for 40 and 15M and the loop as a multiband
80-10M. The pair worked great for me at my location. The loop WAS
supported by four 25-32ft trees. When I tried to improve the system
by raising all the corners of the loop to 32 ft, by using some 32 ft
lengths of metal tubing I pieced together, my 40M vertical did not
seem to work as well. There was not a big difference in the 80-10M
loop it worked fine both setups from what I could tell. Note that I
never used the loop for transmit on 40M as the vertical worked great
and my reason to increase height was not to improve performance of the
loop but for the wire to clear the tops of the trees and not get
tangled as often.
With the metal tubing supporting the corners of the loop it seemed
like the 40Mvertical was a totally different antenna(not as good of
one). As well, resonance the 40M vertical shifted slightly. As my
antenna is in a fairly dense wooded area when it rain heavily or we
have freezing precipitation I also see a similar effect.
The metal vertical support for the corner of the loop was about 37ft
from the base of the 40M vertical. I used this setup over a period of
time and when I removed the metal support tubing , resonance shifted
back on the 40M vertical and it seem to play as it did before , like
the on I home brewed originally.
I'm sure I could have used decoupling techniques so the 40M radiator
did not "see" the vertical elements in close proximity but never did
put the tubing back up when it came down, used much better wire that
didn't tangle.
So how close is to close? I think 37ft was too close for a 40M
vertical in proximity to a 32ft support mast for optimum performance
for the vertical, but if its a second tower I'm sure the gain will be
much better than losses of coupling especially if it means a new 3
element 40Meter monobander as the antenna on the "new tower". I have
ON4UN's Low Band DXing, which is awesome and a must have for all

Ham's, John I believe uses or has used a 160M vertical in the center of a four square, and uses decoupling techniques between the two. If there is an issue with the closeness of the two, decouple at that point. Hope this helps.

MY mistake you would not put a 3element 40m monobander on a 40ft
tower, bad example. Hope the rest helps you,, good DXing.

Virginia,

It is most unlikely that you can connect both a transmitter and a
receiver to the same feedline, it will almost certainly destroy the
receiver.

You can connect two receivers to the same feedline, albeit with some
reduction in performance, but it might not matter much on the lower
parts of HF.

Some, but few, transcievers provide access to the antenna when switched
through to the receiver. If you have that facility, you could use it,
otherwise you could devise some kind of switching arrangement that
reliably prevents the Weatherfax receiver getting a dose of the
transmitter output.

Using a separate antenna for the Weatherfax might seem a solution, but
it needs to provide sufficient isolation so that the energy coupled into
the Weatherfax receiver input is below its damage threshold... and
some.

Owen

There are lots of other options.

The simplest is a switch. Not a home TV antenna switch, but a ham radio or
commercial grade switch.

The second would be an Ameco PT-3 preamp with a the second receiver
modification. The modification is simple and can be easily done.
The downside of it is that it is not desgined to be in a boat (and therefore
not splash resistant), is extra weight, another device that uses 12 volts
and if you are using both at around the same time, they have to be near
each other in frequency.

The advantage is you get an extra 18db gain out of your receive antenna,
a sharply tuned preselector and it automaticly switches the weather fax
out of the circuit when you transmit.

The third is IMHO the best. If you have a computer on the boat, ditch the
weatherfax entirely. Use the receiver of the ham/commerical radio for
the weatherfax and the computer to decode the images.

Note that you can not legally use a ham radio on marine frequencies, BUT
you can use a marine radio on ham frequencies (with the appropriate licenses).

Ham radios with general coverage receivers are small and relatively cheap,
for example the Yaseu FT-817, the ICOM IC-703 or IC-706 and the older (but still
available used) Kenwood TS-50.

If you have a computer, you can also use it to download weather maps,
etc from the internet. If you are close (35km or less) to land, you can
get a cellular modem and out on the open water you can use a satellite phone.
Cellular modems are expensive to use if you are not in an area covered by your
regular carrier, and satellite phones are very expensive to use.

It's a question of whether you want to get your weather information from
a slow, unreliable, but free source (the weatherfax), or a more expensive,
but quicker and more reliable (download) one.

Geoff.

Your radio is not the simplest. There is the LC. The capacitor has the two plates so on the both the voltage is doubled. No matter which one is fed to the headphones.

Could you make the super simplest radio: "Because I have a long (150 foot) antenna, a good ground, and a strong station (50,000 watts) less than 20 miles away, my radio receives enough power to light a low current LED. The LED is a 'high brighness' type (which also means that it will light dimly with a very small amount of current). I connect it instead of diode in the radio, and it glows as the radio operates, getting brighter as the sound gets louder. "

The super simplest radio should consist of an antenna, LED and ground.

Can we reverse the LED?

I am going to listen and think on the subject for a while. I need to
acquire another stick of Rohn 25 anyway.

There is no urgency, I would just like to get back to some VHF work
other than repeaters.

The current tower has a Cushcraft A3S and a 3 element fan dipole that
I find works so good on all bands that I stopped at three. The dipoles
are cut for 17M, 30M, and 80M. I have no idea what is really
radiating when I manually tune up. I always start with minimum
inductance in hopes of fewer tuner losses. I have not tried 160M
though. 40M works well on both antennas so it would not be a big
issue to loose the vertical. It has served more as an all band antenna
than strictly a 40m antenna anyway. The EZNEC patterns for a 30 foot
vertical are not impressive with it, but it does work with an SGC 237
tuner.

I can get the second tower in place with very little cash outlay at
this time. I am leaning towards the project...

And I am expecting a few "issues" along the way.

At 432 mhz, I had better luck with the 300 ohm TV line,
than I did using mediocre CATV cable and a balun.
This was feeding a UHF TV antenna that I used for ATV
on 70 cm. The 300 ohm line had the lower loss of the two.
Until it rained.. Then it was blackout time until it dried.
I have 300 ohm line feeding a 40 m dipole strung up in
the attic. It's an emergency antenna, and I use the 300
ohm line and a tuner to work any band 40-10m.
Being as it never gets wet, it works out pretty well.
300 ohm TV line is usually pretty good. Until it gets wet. :(
In the real world, I generally prefer coax. On the HF bands
it's about all I use. But the 70 cm ATV antenna was one
case where it paid to use the TV line vs coax. Or at
least the coax I had on hand.. Which was Beldon duo-shield
RG-6 type 75 ohm CATV cable.
Going by a gut hunch, I'd say the twin lead is probably
better than mediocre coax on 1296 mhz. You would need
some fairly high quality coax to equal the loss performance
of even cheap 300 ohm line on 1296 mhz. Or I would think
anyway, judging by it's use on 70 cm. I would think the
advantage would become more lopsided towards the 300 ohm
line, the higher in frequency you go.
I could look up the appx numbers in a book, but I'm too
lazy to get up out of my chair. :/

Thanks Geoff. We do plan on getting weather fax on the computer too (we have a pactor modem and sailmail subscription) but since we had the older separate fax machine we thought it would be good to have it running as a backup. So thank you for all the options.

Tom, if he using "an Icom AH-4 Antenna Coupler" on 1296, he's got more
problems than 300 ohm twinlead. :-)

But I take it that your picture still applies to single-core conductors,
and very fat conductors at that.

With the feedline I have in mind, S=55mm and d=1.2mm, so S/d=27.5, which
is way off the end of the scale in your picture.

An interesting bit of trivia for the models I created is that the flux coupling coefficient doesn't vary much with turns for a given diameter and coil pitch.

When you make relatively large diameter coils of fine pitch, k is higher, and that creates the conditions for higher loss in shorted turns.

The implication for long loose coils is that k is low, mutual inductance is low, inductance approaches a constant L per unit length etc.

Sensibly, most air cored solenoids operate in the midrange.

Owen

Hello, and just to tack on to the other comments: If the second antenna's presence changes the feedpoint impedance of the first antenna, you can be sure the second antenna is in the induction (close coupling (non-radiating)) field of the first antenna. If the second antenna could be located about 2-3 wavelenghts from the first it would be in the far-field and its contribution to the radiation pattern of the first, if any, would be minimal. Alas, since this might not be practical, perhaps some modeling using NEC/EZNEC prior to antenna installation would allow for some optimum trade-offs regarding parasitic effects introduced by the second antenna with the goal of saving time (and money). Sincerely, and 73s from N4GGO,

I haven't read all the thread.

I always see the diode in series between the antenna and the headphones.

You will get a much louder audio signal if you connect a germanium diode
( 1N34 ) in parallel with the phones.

The diode (plus leads) is much longer than the total movement of the
electrons at RF. Exactly how many electrons are "flowing" through the
diode during each RF cycle?

Correct.

Then your approximation formula will be fine.

I'll give you the meter leads and you can stand out there while the
storm is approaching and we'll see what the voltage is due to the
storm. the dc voltage due to the radio transmitter is still zero.
